## ABSTRACT

In this study we analyzed blood samples collected from 400 high risk patients for the prevalence of an inflammatory viral disease hepatitis B virus (HBV) and hepatitis C virus (HCV) with the help of standard kit assay and Enzyme-linked immunosorbent assay (ELISA). All the samples were selected randomly from the various places of District Gujrat, Pakistan. All the selected cases were first divided into four groups according to the age and sex (Group 1, Male below age 35 years; Group 2, Male above age 35 years; Group 3, Female below age 35 years; Group 4, Female above age 35 years), each group was comprised of 100 individual patients and analyzed for different parameters for the presence of HBV and HCV in comparison with positive and negative controls. The prevalence of HBV and HCV was higher in groups 2 (22%) and 4 (39%) respectively. Assay profile revealed that the incidence of HCV was higher in female patients as compare to the male patients. The present study indicates that more than 60% of the cirrhosis and hepatocellular carcinoma in the Region is attributable to hepatitis B virus (HBV) or hepatitis C virus (HCV) infection.

**Keywords:** HBV; HCV; Liver Inflammation; LFTs; ELISA; ALP; Bilirubin

## 1. INTRODUCTION

Viral hepatitis is frequently fatal and one of commonest liver infectious (inflammatory) disease across the world [1]. Worldwide, probably 2 billion and 350 to 400 million people are chronically infected with this viral infection [2,3]. Approximately 170 million people throughout the world have chronic HCV infection and that 3 - 4 mil-

lion people are newly infected each year. Hepatitis B and C virus is present in blood, saliva, semen, vaginal secretions, menstrual blood, and to lesser extent, breast milk, and urine of infected individuals [4]. A highly resilient virus, HBV or HCV can easily transmit through contaminated blood transfusion, surgical instruments, dental surgery, sexual contacts and drug abuses, sharing of the house hold items like shaving razors, toothbrushes and also shaving from the barber [4-6].

Patients with slightly elevated ALT (1 - 2 times than the normal limit) are more likely to have transient elevation not because of the disease; however, about 30% of those with chronic HCV infection have peak ALT. In developing countries where resources and facilities may be significantly limited, the prevalence of HBV or HCV is higher as compared to the developed world [7]. In adults daily production of un-conjugated bilirubin is about 250 to 350 mg, normal values is 5 mg/kg/day, or about 400 mg/day. However in comparison to the un-conjugated the level of conjugated bilirubin is highly specific for liver disease. The serum bilirubin level is mainly associated with the extent of hepatocellular necrosis. In this regard further studies are needed to characterize the epidemiology of HBV and HCV transmission, especially in Pakistan.

The present study was conducted to investigate the incidence/prevalence of Hepatitis B and C virus in District Gujrat, Pakistan. In this study, we have analyzed a wide range of patients belonging to various health risk groups for the prevalence of HBV and HCV infection.

## 2. MATERIALS AND METHODS

### 2.1. Sample Collection

Total 400 clinically diagnosed patients were consecutively recruited for the study from various places of District Gujrat Hospitals, Pakistan. Patients were considered to have hepatitis B or hepatitis C infection if their ELIZA

\*Corresponding author.

or screening test was positive and had raised alanine-aminotransferase (ALT) level.

## 2.2. Blood Samples

Up to 5 mL blood was drawn using sterilized disposable syringes from each patient and immediately transferred into the EDTA (anticoagulant) containing tubes. The samples were thoroughly mixed and finally centrifuged at 3000 g for 5 min. Separated serum fractions were transferred into sterilized eppendorf tubes and stored at -20°C until further use.

## 2.3. Determination of Hepatitis B Surface Antigen

For the purpose of quantitative determination of Hepatitis B surface antigen from a separated serum of all the selected samples, RBP4 (human) ELISA Kit was used in vitro. In this procedure the antigen is "trapped" between two layers of enzyme specific antibodies. The whole reaction is followed by a wash and enzyme activity of the bound material in each Microtiter well is determined by adding the substrate of the enzyme.

## 2.4. Liver Function Test (LFT) Profile

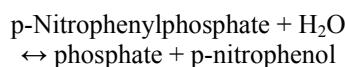

For qualitative detection of HbsAg in whole blood and serum, hepatitis B surface Antigen (HbsAg) was screened out by the use of Trinity Biotech Uni-Gold HbsAg test kit *in vitro*. Serum samples were further analyzed for bilirubin (conjugated and unconjugated), and Alkaline phosphatase (ALP).

### 2.4.1. Bilirubin

The total bilirubin in serum and plasma was determined by the method of coupling with diazotized sulfanilic acid (29 mmol/L) after the addition of caffeine (130 mmol/L), sodium benzoate (156 mmol/L) and sodium acetate (460 mmol/L). Absorbance was recorded using spectrophotometer at 578 nm. The direct and indirect bilirubin level was measured according to the method described by Sather *et al.* [8].

### 2.4.2. Alkaline Phosphatase

To determine the ALP level in the separated serum fractions of all patients, Human Gasellschaft fur Biochemica und Diagnostica mbH (EC 3.1.3.1) kit method was used. Reaction principle is given below:

## 2.5. Immunochromatographic Test (ICT)

Immunochromatographic tests strips were obtained from accurate and Acon (Acon, USA). Strips were used ac-

cording to the manufacturer's instructions for the purpose of HCV screening in all of the separated serum fractions samples.

## 3. RESULTS AND DISCUSSION

To investigate the prevalence of HBV, all of the selected patients were first screened for the presence of HbsAg in the sera. The screening assay profile showed that total 31 cases were positive among all of the 400 analyzed samples. In comparison to the HBV the incidence of HCV was little higher among all groups and total 93 cases were HCV positive from all of the total 400 analyzed samples (**Supplementary Table 1-4**).

### 3.1. Group 1 (Male below Age 35 Years)

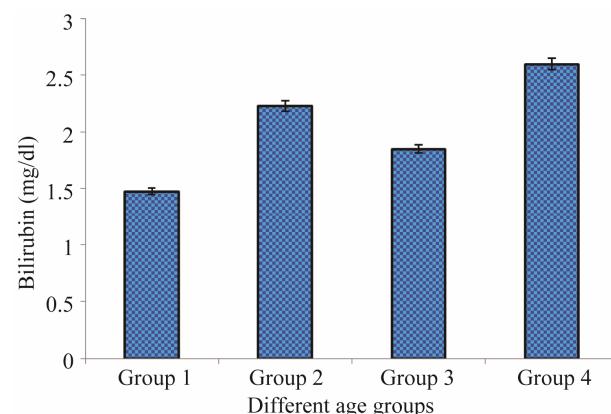

In this group out of the 100 selected samples only 6% were those having their HBV positive test. In the same group 14% patients were highly affected with HCV. Bilirubin assay profile showed that total 18% patients had the higher Bilirubin level ( $1.48 \pm 1.94$ ) as compare to the normal value (up to 1.2 mg/dl) (**Figure 1**). While other, 23% had the higher value of Alkaline phosphatase ( $345 \pm 18$ ) than that of the normal limits (80 - 306 U/L), (**Figure 2**).

### 3.2. Group 2 (Male above Age 35 Years)

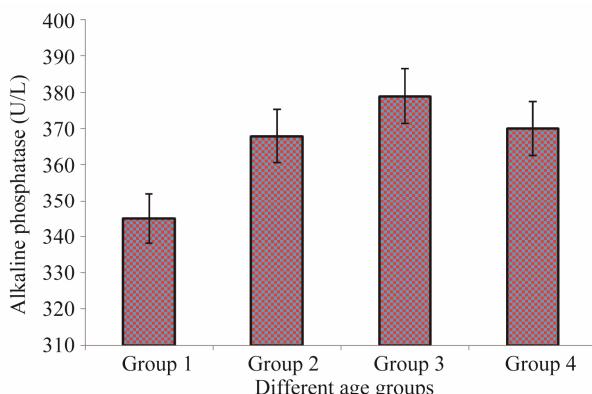

This age group contained HBV and HCV positive ratio 10% and 26% respectively, out of the total 100 randomly selected samples. Bilirubin test assay revealed that 28% had the higher level of Bilirubin with maximum of  $2.23 \pm 16$  mg/dl than the normal value while, other 37% had the higher value of Alkaline phosphatase ( $368 \pm 92$ ) in comparison to the normal limits (**Figures 1-2**).

### 3.3. Group 3 (Female below Age 35 Years)

In this group the prevalence of HBV was 50% lower as compare to the group 1 (Male below age 35 Years) but

**Figure 1.** Bilirubin levels in patients of different age groups.

**Figure 2.** ALP levels in patients of different age groups.

the incidence of HCV positive cases was surprisingly high in comparison to the same age group of males. Out of 100 patients 22% had the higher level of Bilirubin ( $1.85 \pm 24$ ) than that of the normal limits (**Figure 1**). Total 30% were found to have higher value of Alakaline phosphatase ( $379 \pm 19$ ) than its normal limits (80 - 306 U/L) (**Figure 2**).

### 3.4. Group 4 (Female above Age 35 Years)

In comparison to the all other three groups the patients belong to this group were highly affected with HBV and HCV. Total occurrence of HBV and HCV positive percentage was 12 and 30% respectively. In this age group 38% patients have higher level of Bilirubin ( $2.6 \pm 11$ ) while, 45% have higher level of Alakaline phosphatase ( $370 \pm 56$ ) as compare to the normal limits (**Figures 1-2**).

Many of the earlier studies from various regions of Pakistan have reported high prevalence of HCV (20.5% - 60%), [9,10]. The poor dental procedures are the major source of HBV or HCV exposure (39.7%) that is followed by injections (16.6%) and finally the surgical unsterilized items (16.6%) [11]. In an earlier study, Herve [12] reported that the transmitting risk of these viruses has drastically been reduced by screening for their antibodies before blood transfusion. In the present study we observed higher level of Bilirubin that indicates the biliary inflammation, which may be intrahepatic or extra hepatic and this increased value of Bilirubin, is related to liver hepatitis [13]. In the present study serum ALP values were little higher than many of the previously conducted studies.

Our data suggest that the prevalence of HBV and HCV infection was higher in person with age higher than 35. Similar findings have also been reported previously by Leung [14]. It has been reported in literature that blood transfusion continues to cause hepatitis B or C in those countries, where donor blood is not screened for HBV [15]. The present study indicates that blood transfusion is

taking part in transmission of viral infection. Previously, HBV transmission by blood transfusion has also been reported in Pakistan by [16].

## 4. CONCLUSION

Lack of proper blood screening facilities and unawareness about the possible transmission routes of HBV and HCV are contributing a great deal towards the spread of the infection among the population. In this regard further studies are needed to characterize the epidemiology of HBV and HCV transmission, especially in Pakistan.

## 5. ACKNOWLEDGEMENTS

The present work was a part of M.Sc. research work conducted by Mr. Muhammad Naem Raza. On providing technical expertise and collaborative help for the present study, Z. Anwar is thankfully acknowledged.
