ABSTRACT

Soil heat flux is an inseparable component of the surface energy balance. Accurate estimation of regional soil heat flux is valuable to studies of meteorology and hydrology. Conventional measurement of using soil heat flux plates at the site scale is impractical to estimate large-scale flux. Other approaches generally require soil temperature to be measured in at least two soil layers, which is also difficult to implement at the regional scale. In the last decade, single-layer based approaches were developed to fulfill the regional requirement. This study used a simple but more general approach for estimating soil heat flux solely with surface temperature. The generalized approach can be conditionally linked to two existing single-layer based approaches but has fewer restrictions or assumptions. Error analysis revealed that measurement error in surface temperature would have limited effects on soil heat flux estimated from the new approach. Model simulations showed that soil heat flux estimated from the approach agreed with those simulated from the heat transfer equation. Furthermore, case examinations at two sites with contrasting climate regimes demonstrated that the generalized approach had better performance than the existing single-layer approaches. It achieved the highest correlation of determination and the lowest mean, standard deviation, and root mean squared error of the differences between the estimates and the field measures at either site. The generalized approach can estimate soil heat flux at a depth but it requires only surface temperature data as input, which is an advantage to remote sensing applications.

Soil Heat Flux; Land Surface Temperature; Remote Sensing

1. Introduction

In daytime, solar radiation warms the land surface. Except for evaporation loss and turbulent heat exchange with air, a part of this heat is transferred into the soil. Soil heat is an inseparable component of surface energy balance and becomes a major term in the under-story energy budget at night [1]. Accurate estimation of soil heat flux is highly valuable for studies in a number of fields, including meteorology, hydrology, and agriculture.

Soil heat flux plates can be used to determine soil heat flux at a site scale. The accuracy, however, is affected by the embedded depth of the plate, the thermal property

variation of the soil, and the upward migration of water [2-4]. Various approaches have been developed to estimate soil heat flux, including those based on the rate of soil heat storage change [5] and those that calculate surface soil heat flux as the residual of the energy balance equation or as a ratio of net radiation [6]. Another approach involves direct or indirect application of the Fourier's law. Directly, soil heat flux is calculated from the temperature gradient using multi-layer observation data [7-10]. Alternatively, the Fourier's law can be coupled with the heat transfer equation to obtain a solution. Li *et al.* [11], Tanaka *et al.* [12], and Yang and Wang [13] derived profiles of soil moisture and temperature from the heat flow equation and then integrated these profiles

to parameterize soil heat flux. However, most approaches have several shortcomings when estimating soil heat flux at a large scale. First, soil temperature must be measured in no less than two layers. Second, the empirical formulations adopted in conventional approaches generally have spatial and temporal limitations and thus are difficult for practical use in other areas [14,15]. In general, such shortcomings do not allow the existing approaches to be used for regional estimation.

Single-layer based approach was developed to fulfill the regional requirement. Horton and Wierenga [5] described an approach to determine soil heat flux at different depth only from the upper boundary temperature, based on Van Wijk's Fourier series [16]. This approach can be used to estimate soil heat flux at regional scale [17]. The key to the approach is the determination of the harmonics number in expressing soil temperature. The determination often requires performing a Fourier series analysis of in situ data of temperature, which is not easy to implement for long-term large-scale monitoring in practice. In recent years, Wang and Bras [18] used a half-order derivative solution of the heat flow equation and proposed a method to estimate soil heat flux using time series data of soil temperature at the corresponding depth. It performed well in estimating ground or soil heat flux [18-22]. Notably, the approach requires soil heat flux being estimated from the soil temperature at the same depth. This requirement may become a disadvantage for estimating heat flux at a depth different from the used soil temperature.

Satellite remote sensing now provides routine retrievals of land surface temperature (LST) at a global scale [23,24]. For better use of surface information, we generalized a simple approach to estimate soil heat flux, based on the heat transfer equation and Duhamel's integral. The approach uses only surface temperature to estimate soil heat flux at a depth. Through mathematical analysis, conditional linkages were established between the generalized approach and the existing single-layer based ones. Simulation work and error analysis were also performed to demonstrate the robustness of the approach. Field observation data were then used to verify and compare these approaches. At last, the strength and weakness of each approach were discussed for their possible application to large-scale monitoring of soil heat flux.

2. Methodology Development

Based on heat transfer equation, the Duhamel's integral is used to derive a simple approach for estimating soil heat flux from surface temperature. Its linkage to the existing single-layer based approaches is then established. Error analysis is further applied to test the robustness of the approach in regard to surface temperature measures.

2.1. Derivation of a Simple Approach for Estimating Soil Heat Flux from Surface Temperature

For a semi-infinite solid, bounded by a surface ($z = 0$) with extension to infinity in depth z , given a uniform initial temperature (T_0) profile throughout the entire soil layer, the heat transfer process in the soil system can be described as

$$\frac{\partial T}{\partial t} = a \frac{\partial^2 T}{\partial z^2}, \quad (1a)$$

$$T = T_0, \text{ for } t = 0, z < 0, \quad (1b)$$

$$T = T_0, \text{ for } t > 0, z \rightarrow -\infty, \quad (1c)$$

$$T_s = T_s(t), \text{ for } t > 0, z = 0, \quad (1d)$$

where a is thermal diffusivity, T is soil temperature at depth z , and $T_s(t)$ is surface soil temperature varying with time. We set $T^* = T - T_0$, and Equations (1) is simplified to

$$\frac{\partial T^*}{\partial t} = a \frac{\partial^2 T^*}{\partial z^2}, \quad (2a)$$

$$T^* = 0, \text{ for } t = 0, z < 0, \quad (2b)$$

$$T^* = 0, \text{ for } t > 0, z \rightarrow -\infty, \quad (2c)$$

$$T_s^* = T_s(t) - T_0, \text{ for } t > 0, z = 0. \quad (2d)$$

This is a heat conduction problem with boundary temperature continuous in time. Such a problem can be solved with Duhamel's theorem [25]. According to the theorem, if $\varphi(x, t)$ is the response of a linear system with a zero initial condition to a single, time-invariant non-homogeneous term with magnitude of unity (referred to as the fundamental solution), then the response of the same system, $\psi(x, t)$, to a time-varying non-homogeneous term with magnitude $B(t)$ can be obtained from the fundamental solution according to,

$$\psi(x, t) = \int_{\tau=0}^t \varphi(x, t - \tau) \frac{dB}{d\tau} d\tau + B|_{\tau=0} \varphi(x, t), \quad (3)$$

where $B|_{\tau=0}$ is the value of B at time zero and B must be continuous in time.

Likely, the solution of Equations (2) and (3) is given as

$$T^*(z, t) = \int_{\tau=0}^t \varphi(z, t - \tau) \frac{dT_s^*}{d\tau} d\tau + T_s^*|_{\tau=0} \varphi(z, t), \quad (4)$$

where τ is the integral variable, $\varphi(z, t)$ is the solution of the heat conduction problem with zero initial condition and a unity, time-invariant surface boundary temperature,

$$\frac{\partial \varphi}{\partial t} = a \frac{\partial^2 \varphi}{\partial z^2}, \quad (5a)$$

$$\varphi = 0 \text{ for } t = 0, z < 0, \quad (5b)$$

$$\varphi = 0 \text{ for } t > 0, z \rightarrow -\infty, \quad (5c)$$

$$\varphi = 1 \text{ for } t > 0, z = 0. \quad (5d)$$

Since $\varphi(z, t)$ is easy to solve using the separation of variables technique [26,27], we then have

$$\varphi(z, t) = 1 - \frac{2}{\sqrt{\pi}} \int_0^{\frac{-z}{2\sqrt{at}}} e^{-\tau^2} d\tau. \quad (6)$$

Substituting Equation (6) into Equation (4), we get

$$T^*(z, t) = \int_0^t \left(1 - \frac{2}{\sqrt{\pi}} \int_0^{\frac{-z}{2\sqrt{a(t-\tau)}}} e^{-s^2} ds \right) \frac{\partial T_s^*(\tau)}{\partial \tau} d\tau + T_s^* \Big|_{t=0} \left(1 - \frac{2}{\sqrt{\pi}} \int_0^{\frac{-z}{2\sqrt{at}}} e^{-\tau^2} d\tau \right). \quad (7)$$

With the initial surface temperature $T_s^* \Big|_{t=0} = T_0 - T_0 = 0$, we can obtain

$$T^*(z, t) = \int_0^t \left(1 - \frac{2}{\sqrt{\pi}} \int_0^{\frac{-z}{2\sqrt{a(t-\tau)}}} e^{-s^2} ds \right) \frac{\partial T_s^*(\tau)}{\partial \tau} d\tau. \quad (8)$$

Resetting variable $T = T^* - T_0$, subsequently we have

$$T(z, t) = T_0 + \int_0^t \left(1 - \frac{2}{\sqrt{\pi}} \int_0^{\frac{-z}{2\sqrt{a(t-\tau)}}} e^{-s^2} ds \right) \frac{\partial T_s^*(\tau)}{\partial \tau} d\tau. \quad (9)$$

According to the Fourier's law, soil heat flux (G) is proportional to the gradient of soil temperature (T), taking downward heat transfer as positive,

$$G = k \frac{\partial T}{\partial z}, \quad (z < 0). \quad (10)$$

Combining Equations (9) and (10), we then get vertical soil heat flux

$$G(z, t) = \sqrt{\frac{kC_s}{\pi}} \int_0^t \frac{1}{\sqrt{t-\tau}} e^{-\frac{z^2}{4a(t-\tau)}} dT_s(\tau), \quad (11)$$

where $T_s(\tau)$ is surface soil temperature, τ is the integration variable, k is the heat conductivity ($\text{J}\cdot\text{m}^{-1}\cdot\text{s}^{-1}\cdot\text{K}^{-1}$), and C_s is the volumetric heat capacity of soil ($C_s = k/a$). With Equation (11), we can estimate soil heat flux at any depth only from time series data of surface temperature when soil thermal properties are known.

In the following analysis, we make inferences to establish the linkages of Equation (11) to the existing single-layer approaches. One is by Wang and Bras [18] (hereafter referred to as W-B approach), and another is

$$G(z, t) = k \sum_{n=1}^{\infty} C_{on} \sqrt{n\omega/a} e^{z\sqrt{n\omega/2a}} \sin\left(n\omega t + z\sqrt{n\omega/2a} + \beta_{on} + \frac{\pi}{4}\right) - k \frac{\partial}{\partial z} \left(\frac{2}{\sqrt{\pi}} \sum_{n=1}^{\infty} C_{on} \int_0^{-z/\sqrt{4at}} e^{-\eta^2} \sin\left(n\omega \left(t - \frac{z^2}{4a\eta^2}\right) + \beta_{on}\right) d\eta \right). \quad (18)$$

by Horton and Wierenga [5] (hereafter referred to as H-W approach).

If the soil at depth z_0 is set to be the upper boundary of the soil system, *ceteris paribus*, Equation (11) is expanded as

$$G(z, t) = \sqrt{\frac{kC_s}{\pi}} \int_0^t \frac{1}{\sqrt{t-\tau}} e^{-\frac{(z-z_0)^2}{4a(t-\tau)}} dT(z_0, \tau), \quad (z \leq z_0 \leq 0) \quad (12)$$

where $G(z, t)$ is soil heat flux at a deep layer below z_0 , and $T(z_0, \tau)$ is soil temperature at z_0 . This means that the soil heat flux below can be obtained from time series of soil temperature at a certain depth. Inferentially, from Equation (12) soil heat flux at depth z is expressed as the integration of soil temperature at the same depth

$$G(z, t) = \sqrt{\frac{kC_s}{\pi}} \int_0^t \frac{dT(z, \tau)}{\sqrt{t-\tau}}. \quad (13)$$

Equation (13) is identical to that in the W-B approach, which was deduced with a half-order derivative/integral operator [18].

In the H-W approach, surface temperature is assumed as

$$T_s^*(t) = \sum_{n=1}^{\infty} C_{on} \sin(n\omega t + \beta_{on}), \quad (14)$$

where C_{on} is the amplitude of the n^{th} harmonic of surface temperature, and β_{on} is the n^{th} phase constant. From Equation (8), we may have

$$T^*(z, t) = \frac{-z}{\sqrt{4\pi a}} \int_0^t \frac{T_s^*(\tau)}{(t-\tau)^{3/2}} e^{-\frac{z^2}{4a(t-\tau)}} d\tau. \quad (15)$$

If we define $\eta = \frac{-z}{\sqrt{4a(t-\tau)}}$, $d\tau = \frac{2}{\eta}(t-\tau)d\eta$, then

Equation (15) becomes

$$T^*(z, t) = \frac{2}{\sqrt{\pi}} \int_{-z/\sqrt{4at}}^{\infty} e^{-\eta^2} T_s^* \Big|_{\tau=t-z^2/(4a\eta^2)} d\eta. \quad (16)$$

Substituting Equation (14) into Equation (16), resetting variable $T = T^* - T_0$, we may get

$$T(z, t) = T_0 + \sum_{n=1}^{\infty} C_{on} e^{z\sqrt{n\omega/2a}} \sin\left(n\omega t + z\sqrt{n\omega/2a} + \beta_{on}\right) - \frac{2}{\sqrt{\pi}} \sum_{n=1}^{\infty} C_{on} \int_0^{-z/\sqrt{4at}} e^{-\eta^2} \sin\left(n\omega \left(t - \frac{z^2}{4a\eta^2}\right) + \beta_{on}\right) d\eta. \quad (17)$$

Likely, from Equation (10) we get

The second terms in (17) and (18) are transient processes. When time $t \rightarrow \infty$, they approach zero, leaving the first term which is a series with steady oscillation of periods

$\frac{2\pi}{n\omega}$ [27]. In this case, Equation (18) becomes

$$G(z, t) = k \sum_{n=1}^{\infty} C_{on} \sqrt{n\omega/a} e^{z\sqrt{n\omega/2a}} \sin\left(n\omega t + z\sqrt{n\omega/2a} + \beta_{on} + \frac{\pi}{4}\right). \quad (19)$$

This is identical to the equation used in the H-W approach [5].

It is clear that Equation (13) is a derivative form of Equations (11) and (19) can be derived from Equation (9). In general, Equations (13) and (19) are derivatives of Equation (11). In this way, the generalized approach is linked to the W-B and the H-W approaches.

2.2. Error Propagation of Temperature Measure in the Generalized Approach

In regard to error propagation in Equation (11), if a T_s measure is supposed to be with both systematic and random errors, it can be described as follows

$$T_{s, meas} = T_s + \Delta T_s + \delta T_s, \quad (20)$$

where ΔT_s denotes systematic error (K) and δT_s is random error (K). ΔT_s may be constant or variable. Given that surface measures has a relative accuracy of A ($A = (T_{s, meas} - T_s)/T_s = \Delta T_s/T_s$ and $|A| \leq 1\%$ in most cases), we may have

$$\Delta T_s = A T_s. \quad (21)$$

Further incorporated with Equation (11), we have

$$\begin{aligned} G_{est}(z, t) &= \sqrt{\frac{kC_s}{\pi}} \int_0^t \frac{1}{\sqrt{t-\tau}} e^{-\frac{z^2}{4a(t-\tau)}} d(T_s + A T_s + \delta T_s) \\ &= (A+1) \sqrt{\frac{kC_s}{\pi}} \int_0^t \frac{1}{\sqrt{t-\tau}} e^{-\frac{z^2}{4a(t-\tau)}} dT_s \\ &\quad + \sqrt{\frac{kC_s}{\pi}} \int_0^t \frac{1}{\sqrt{t-\tau}} e^{-\frac{z^2}{4a(t-\tau)}} d\delta T_s \\ &= G + AG + \sqrt{\frac{kC_s}{\pi}} \int_0^t \frac{1}{\sqrt{t-\tau}} e^{-\frac{z^2}{4a(t-\tau)}} d\delta T_s. \end{aligned} \quad (22)$$

Since the last component in Equation (22) is an improper integral, we get

$$\begin{aligned} &\sqrt{\frac{kC_s}{\pi}} \int_0^t \frac{1}{\sqrt{t-\tau}} e^{-\frac{z^2}{4a(t-\tau)}} d\delta T_s \\ &= \lim_{\varepsilon \rightarrow 0^+} \sqrt{\frac{kC_s}{\pi}} \int_0^{t-\varepsilon} \frac{1}{\sqrt{t-\tau}} e^{-\frac{z^2}{4a(t-\tau)}} d\delta T_s. \end{aligned} \quad (23)$$

Based on the First mean value theorem for integration, there exists a value $\xi \in (0, t - \varepsilon)$ such that

$$\begin{aligned} &\lim_{\varepsilon \rightarrow 0^+} \sqrt{\frac{kC_s}{\pi}} \int_0^{t-\varepsilon} \frac{1}{\sqrt{t-\tau}} e^{-\frac{z^2}{4a(t-\tau)}} d\delta T_s \\ &= \frac{\sqrt{kC_s}}{\sqrt{\pi(t-\xi)}} e^{-\frac{z^2}{4a(t-\xi)}} \lim_{\varepsilon \rightarrow 0^+} \int_0^{t-\varepsilon} d\delta T_s \\ &= \frac{\sqrt{kC_s}}{\sqrt{\pi(t-\xi)}} e^{-\frac{(z-z_0)^2}{4a(t-\xi)}} \int_0^t d\delta T_s \\ &= \frac{\sqrt{kC_s}}{\sqrt{\pi(t-\xi)}} e^{-\frac{z^2}{4a(t-\xi)}} \Delta t \sum_{i=1}^N \delta T_{s,i} \end{aligned} \quad (24)$$

where Δt is time interval of T_s measures, N is the total number of measurements. From Equations (22)-(24), we get

$$G_{est} = G + AG + \sqrt{\frac{kC_s}{\pi(t-\xi)}} e^{-\frac{z^2}{4a(t-\xi)}} \Delta t \sum_{i=1}^N \delta T_{s,i}. \quad (25)$$

It is clear that G_{est} is affected by a systematic component AG and a random component

$\sqrt{\frac{kC_s}{\pi(t-\xi)}} e^{-\frac{z^2}{4a(t-\xi)}} \Delta t \sum_{i=1}^N \delta T_{s,i}$. Because δT_s is random error, its mathematical expectation $E(\delta T_i) = 0$. When N is large enough, the random component approaches zero. Providing that temperature measure has a relative error of 1% (approximate 3 K), it would result in 1% error in G_{est} . Therefore, it is expected that errors in surface temperature measure would have limited effects on the estimated soil heat flux.

3. Validation

Both model simulation and field observation were used for validation to test the generalized approach. Soil heat flux estimated from Equation (11) was compared with that simulated using heat transfer equation (Equations (1)) and heat flux equation (Equation (10)). Furthermore, the generalized approach was compared with the W-B approach and the H-W approach using field measures at two contrasting climate regimes.

3.1. Numerical Simulation

As did in Wang and Bras [18], numerical model of Equations (1) and (10) was established to test the generalized approach. To be representative for common soil materials, the coefficients, a used in Equation (1) and k and C_s used in Equations (10) and (11), were set to be $7.2 \times 10^{-7} \text{ m}^2 \cdot \text{s}^{-1}$, $1.0 \text{ W} \cdot \text{m}^{-1} \cdot \text{K}^{-1}$, and $1.4 \times 10^6 \text{ J} \cdot \text{m}^{-3} \cdot \text{K}^{-1}$, respectively. Given a function of T_s , surface soil heat

fluxes can be subsequently calculated at a depth, for example, 5-cm. Meanwhile, Equation (11) was applied to estimate soil heat flux at the corresponding depth.

3.2. Case Examination

We used field data measured at two observation stations. Both sites are in China. The Shouxian site (32.55°N, 116.78°E) is in a humid monsoonal climate, and the Changwu site (35.2°N, 107.8°E) in a semi-arid climate. At Changwu, soil temperatures were measured at 2, 10, 20, and 40 cm depths, and soil heat flux was measured at 5 cm depth. At Shouxian, soil temperatures were observed at 5, 10, 20, and 40 cm, and soil heat flux was measured at 1 cm. Surface soil temperatures were measured with an infrared thermometer installed on a flux tower at each site [28,29]. The infrared thermometers were calibrated with an accuracy of ± 2 K (one Standard Deviation), roughly 0.7% in relative accuracy. All the data were 30-min mean values. In this study, two-week observation data were selected at each site for the period when soil heat flux had large variations. This is, from 10-24 August 2003 at Shouxian, and from 15-29 July 2004 at Changwu.

The generalized approach, the W-B approach and the H-W approach were respectively used to estimate soil heat flux at 1 cm depth for Shouxian and at 5 cm depth for Changwu. The coefficient kC_s used in Equations (11) and (13) was estimated following Wang and Bras [18]. The thermal diffusivity a used in Equations (11), (13) and (19) was estimated from soil temperature measurements using the arctangent approach [30].

The generalized approach (Equation (11)) requires only surface temperature. On the other hand, the W-B approach (Equation (13)) requires soil temperature data at the depth same as that of soil heat flux. Since the data were unavailable, cubic-spline interpolation approach was used to obtain soil temperature at the depth where soil heat flux was measured [1,31]. At Shouxian, $T_{1\text{cm}}$ was interpolated from the temperature data measured at 0, 5, 10, 20, and 40 cm depths. At Changwu, $T_{5\text{cm}}$ was interpolated from the temperature at 0, 2, 10, 20, and 40 cm depths. Following Wang and Bras [18] and Hsieh *et al.* [22], we set the initial values of a soil temperature profile to be uniform and the starting time of integration in Equations (11) and (13) to be the time when soil heat flux was close to zero.

The H-W approach requires a harmonics number and several coefficients used in Equation (19). To achieve satisfied results, the harmonics number was set to be 6 [32], and the coefficients C_{on} and β_{on} were used, not for the whole observation period, but for every 24-hour period in this study. Fourier series analysis was applied to surface temperature data in order to obtain the coefficients [17].

4. Results and Discussion

4.1. Validation of the Generalized Approach

Results demonstrated that surface soil heat fluxes estimated from Equation (11) agreed well with that simulated from the heat transfer model (**Figure 1(a)**). The estimated and the model simulated fluxes had a high coefficient of $R^2 = 0.99$ ($p < 0.001$) (**Figure 1(b)**), with a difference of $2.2 \pm 0.8 \text{ W}\cdot\text{m}^{-2}$ (one S. D.) and a Root Mean Square Error (RMSE) of $2.3 \text{ W}\cdot\text{m}^{-2}$. It confirmed that the generalized approach is comparable to the numerical solution of the heat transfer equation.

Figure 2 illustrates the environmental variations in terms of precipitation and solar radiation at Shouxian (**Figure 2(a)**) and Changwu (**Figure 2(b)**). At the Shouxian site, solar radiation was generally lower than $200 \text{ W}\cdot\text{m}^{-2}$ during rainy periods and reached over $800 \text{ W}\cdot\text{m}^{-2}$ in the later sunny days. At Changwu site, it was generally sunny and solar radiation reached over $1200 \text{ W}\cdot\text{m}^{-2}$ in this period.

Figure 3 shows the temporal variations of soil temperature by depth at Shouxian (**Figure 3(a)**) and Changwu (**Figure 3(b)**). The average soil temperature was generally higher than 25°C at Shouxian. Soil temperature showed the larger variation at Changwu than at Shouxian.

Figure 4 shows the temporal variations of soil heat flux (black line) observed by heat-flux plate at 1-cm depth for Shouxian (**Figure 4(a)**) and 5-cm depth for Changwu (**Figure 4(b)**). The overall average soil heat fluxes were $-2.6 \text{ W}\cdot\text{m}^{-2}$ and $1.3 \text{ W}\cdot\text{m}^{-2}$ at the two sites during the observation periods. The overall average diurnal amplitudes were $44.5 \text{ W}\cdot\text{m}^{-2}$ and $122.9 \text{ W}\cdot\text{m}^{-2}$, respectively. In daytime, the soil heat flux was generally higher at the Changwu site than at the Shouxian site.

The soil heat flux estimates from Equation (11) (blue dot) basically agreed well with the observed values at both sites (**Figure 4**). At Shouxian, the estimated values from Equation (11) agreed with the observed values ($R^2 = 0.92$) ($p < 0.001$) (**Figure 5(a)**), with a difference of $0.17 \pm 4.9 \text{ W}\cdot\text{m}^{-2}$ (**Table 1**). The RMSE was $4.9 \text{ W}\cdot\text{m}^{-2}$. At Changwu, the estimates from Equation (11) agreed with the observed values ($R^2 = 0.89$) ($p < 0.001$) (**Figure 6(a)**), showing a difference of $0.0 \pm 13.4 \text{ W}\cdot\text{m}^{-2}$, with a RMSE of $13.3 \text{ W}\cdot\text{m}^{-2}$ (**Table 1**). Clearly, Equation (11) showed comparable performance in estimating soil heat flux at both Shouxian with a humid monsoonal climate and Changwu with a semi-arid climate.

4.2. Comparative Analysis of Three Approaches

The estimates of soil heat fluxes from the proposed, the W-B, and the H-W approaches are shown in **Figure 4**. The values from the proposed method Equation (11) were indicted with blue dot. The values from the W-B

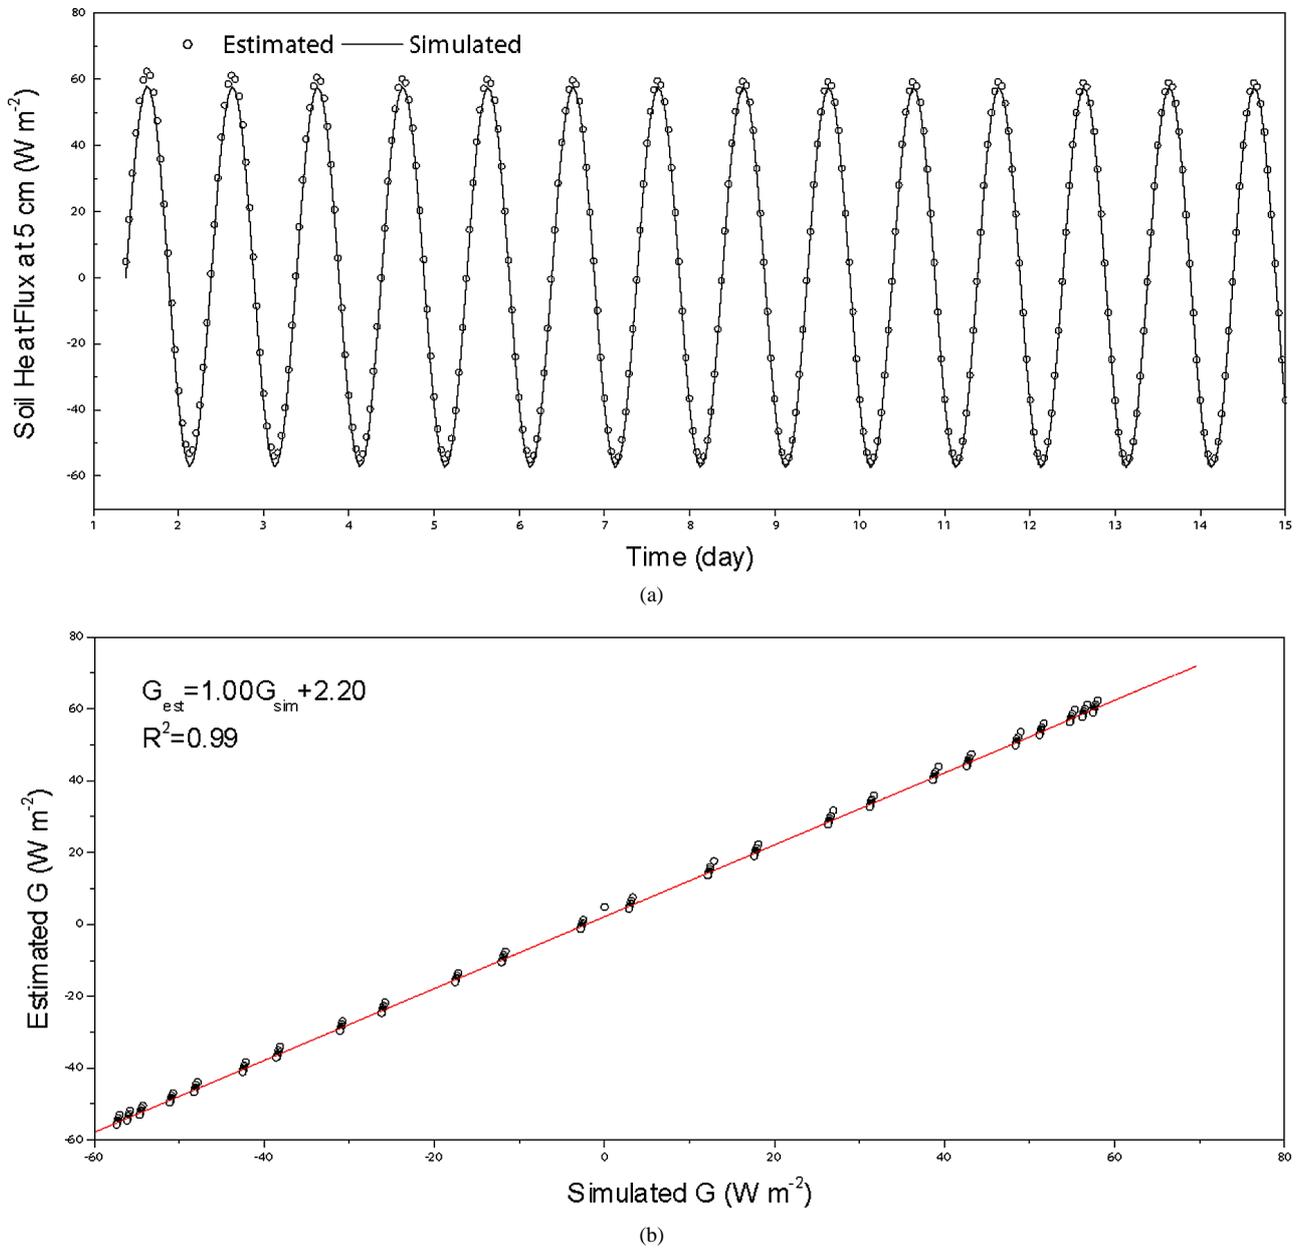

Figure 1. Comparison of soil heat flux simulated from the heat transfer model and that estimated from the proposed equation (Equation (11)). (a) Time series of the model simulated and the estimated soil heat fluxes; (b) The model simulated versus the estimated soil heat flux.

approach were in red line and from the H-W approach in olive-line forms. The temporal variations of the observed and estimated soil heat flux are the evidence that all the three approaches agreed with the observation. The scatter plots of the estimated against the observed values confirmed the agreements (Figures 5 and 6). The values were distributed around 1:1 line. The slopes of regression lines were quite close to unity.

Among the three approaches, the proposed method showed best performance for both sites. The regression equations between the estimated values by Equation (11)

and the measured values were $G_{est} = 1.00G_{obs} + 0.18$ for Shouxian and $G_{est} = 1.00G_{obs} - 0.0$ for Changwu. It had the highest correlation coefficient R^2 and the lowest mean, S.D. and RMSE among the three approaches for both sites (Table 1).

The W-B approach performed well at Shouxian site (Figure 5(b)) but was less effective at Changwu. At Shouxian site, it had a difference to the observed values by $0.39 \pm 5.1 \text{ W}\cdot\text{m}^{-2}$. The R^2 value was 0.92 ($p < 0.001$) and the RMSE was $5.2 \text{ W}\cdot\text{m}^{-2}$, very close to that by the generalized approach. At Changwu site, the difference

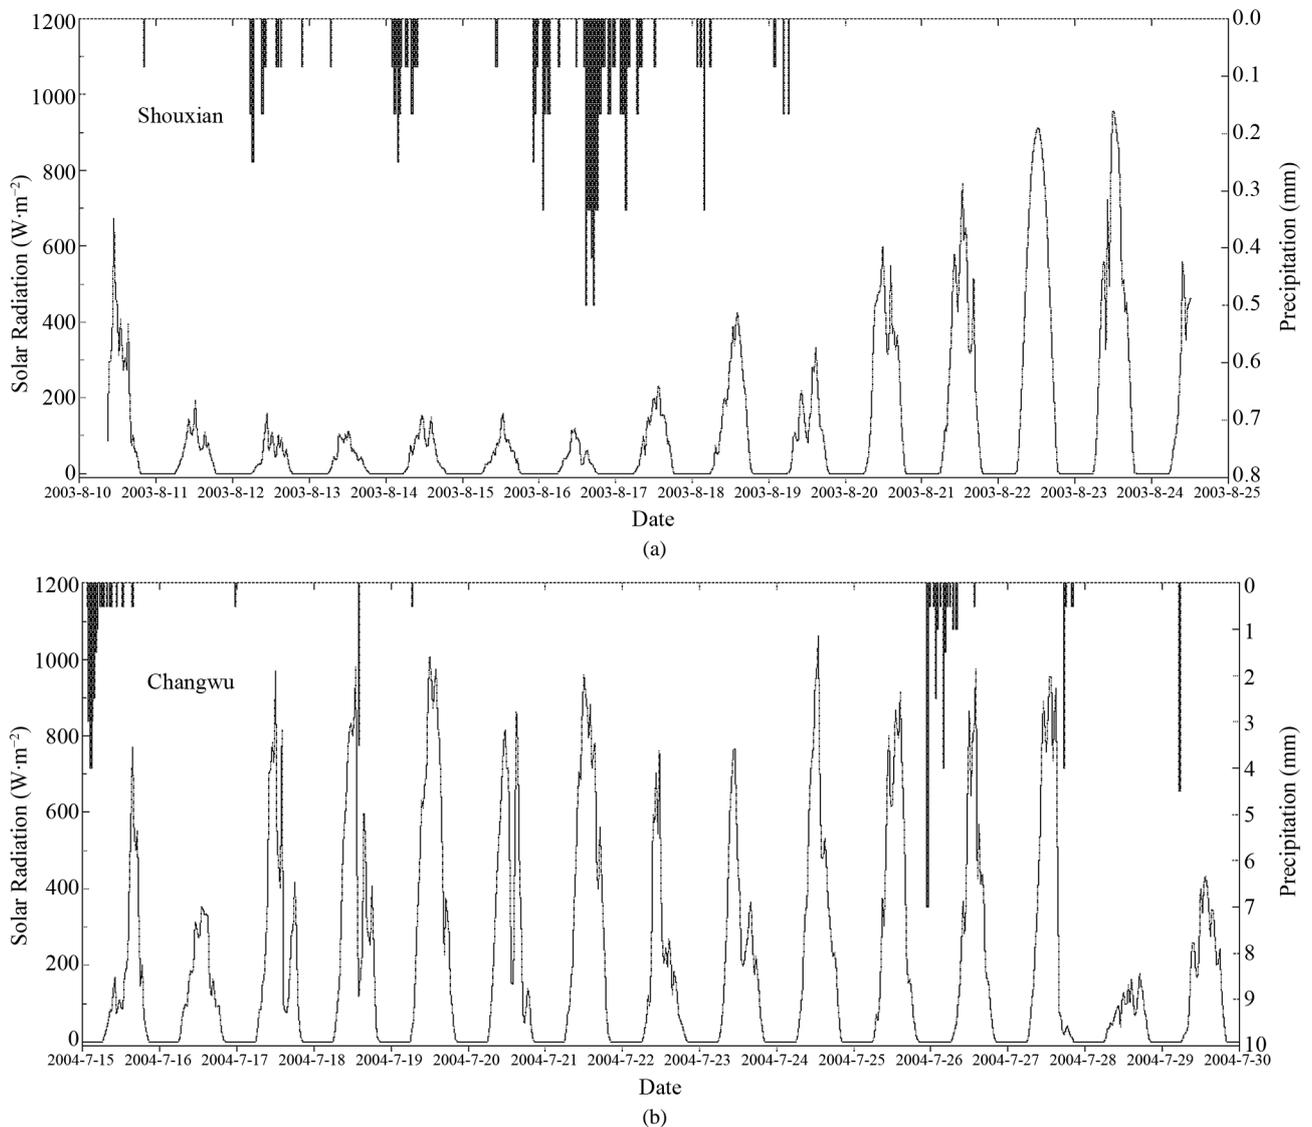

Figure 2. Environmental variations in terms of solar radiation and precipitation during the observation period at Shouxian (a) and Changwu (b) of China.

was $-3.33 \pm 27.5 \text{ W}\cdot\text{m}^{-2}$. The R^2 value was low by 0.67 ($p < 0.05$), and the RMSE value was $27.7 \text{ W}\cdot\text{m}^{-2}$, more than two times of that by the generalized approach.

The H-W approach did not perform as well as that by the W-B approach at Shouxian. It had a difference to the observed values by $1.80 \pm 14.2 \text{ W}\cdot\text{m}^{-2}$. The R^2 value between the estimates and the measures was 0.57 and the RMSE was $14.6 \text{ W}\cdot\text{m}^{-2}$. On the other hand, it achieved good performance at Changwu with a difference of $-1.3 \pm 18.5 \text{ W}\cdot\text{m}^{-2}$, a R^2 of 0.83 ($p < 0.01$) and a RMSE of $18.7 \text{ W}\cdot\text{m}^{-2}$. It showed better performance than the W-B approach at Changwu.

4.3. Evaluation of Three Approaches

From section 2.1, it is clear that the W-B approach and

the H-W approach are derivative forms of the generalized approach. However, comparative analysis revealed the approaches showed different performance in estimating soil heat fluxes at either testing sites. In the section, we will make further analysis to investigate what should account for the differences in estimation.

The generalized approach achieved a high agreement with the observed soil heat flux. The errors in the estimation can be related to the measurement errors in land surface temperature and soil heat flux, the estimation of the coefficients representing soil thermal properties, and the assumptions used in derivation of the generalized approach as well. In the derivation of Equation (11), we assumed soil to be homogeneous and no internal heat sources exist. Homogeneity assumption requires soil ther-

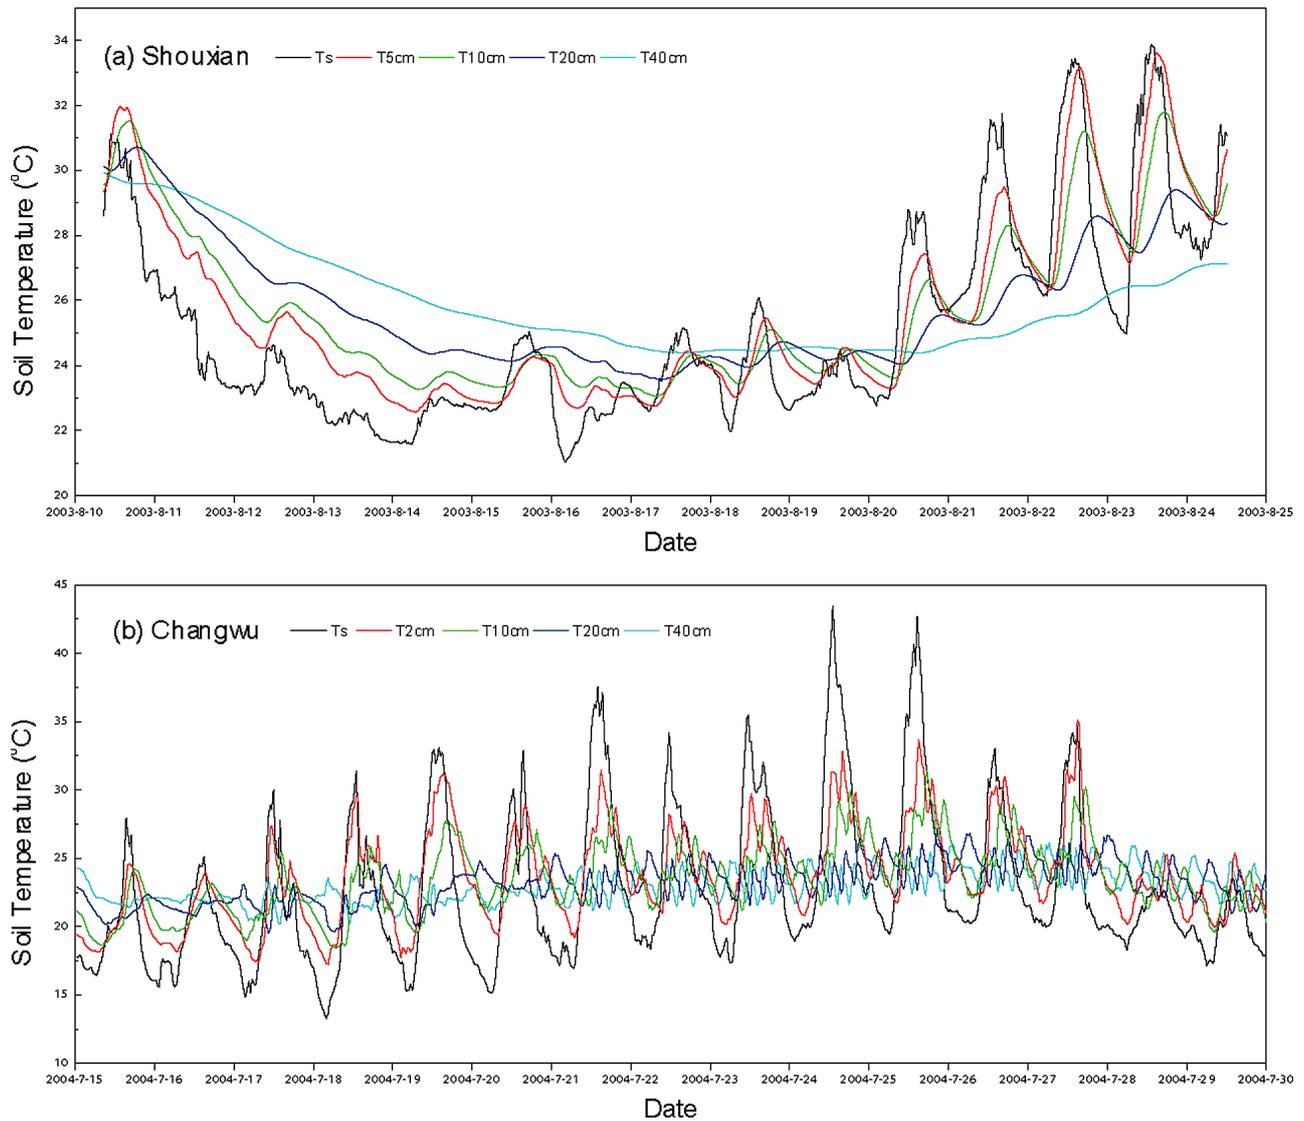

Figure 3. Temporal variations of soil temperatures by depth at Shouxian (a) and Changwu (b) of China during the observation periods.

mal properties, including heat conductivity k , heat capacity C_s and/or thermal diffusivity a , be invariant in space and time. In the present study, we used the same values for all the approaches. Our results showed that the estimated k , C_s and a values were relatively constant for different layers at Changwu or Shouxian. Consequently, the differences between different approaches were unlikely related to the homogeneity assumption and estimation errors in the coefficients.

The W-B approach achieved comparable results to the generalized approach at Shouxian site, but less comparable results by a difference of $-0.69 \pm 14.1 \text{ W}\cdot\text{m}^{-2}$ at Changwu site. The difference between the generalized approach and the W-B approach was that the later required soil temperature to be measured at the same depth as that of the estimated soil heat flux. This is generally

unavailable at a large scale, and its application is thus limited to cases when estimating soil heat flux on surface. In the present study, soil temperature data were unavailable at the same depth as the soil heat flux measurement at either Shouxian or Changwu. Thus, the cubic-spline interpolation approach was used to obtain the required soil temperature. The statistically-based approach may generate errors in the interpolated temperature. For example, in the case of Shouxian, the vertical distribution of soil temperature was relatively stable within a relatively narrow range of temperature during the observation period. **Figure 7(a)** shows a one-day case. In the case of Changwu, surface soil temperature had a relatively large variation within a relatively wide range of temperature. The large fluctuations tended to increase the errors in the interpolated temperature compared to that at Shouxian (**Fig-**

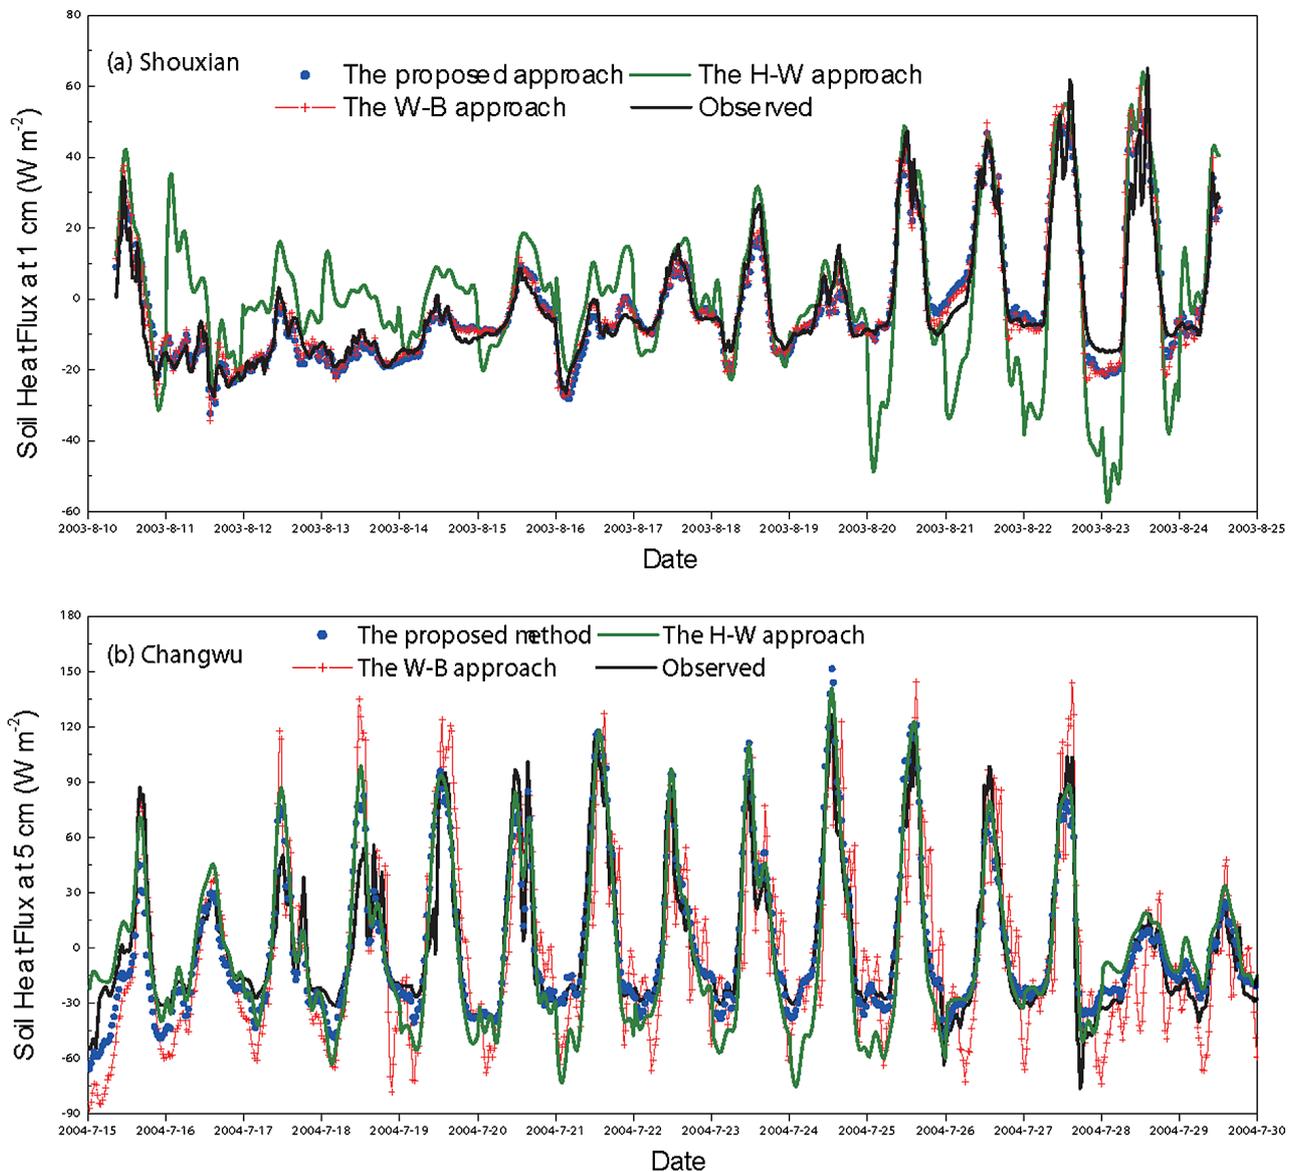

Figure 4. Temporal variations of soil heat fluxes observed (black line) and estimated from the generalized approach (blue dot), the W-B approach (red line) and the H-W approach (olive line) at a depth of 1-cm at Shouxian (a) and 5-cm at Changwu (b) of China during the observation period.

ure 7(b)). The interpolation errors were responsible for the resulted errors in soil heat flux, especially at Changwu.

Compared the generalized approach, the H-W approach did not achieve satisfactory results at Shouxian as it did at Changwu. Its difference to the generalized approach was that it assumed soil temperature and soil heat flux varied harmonically with time. This hypothesis is not always fulfilled, particularly in regions where abrupt weather change occurs within a short time, for example, during the crossover of a cold front [33]. Furthermore, the H-W approach requires determination of harmonics number. Although it was declared that any periodic varia-

tion could be well simulated if the number was large enough, in practice only limited number can be used and this would inevitably introduce errors, sometimes quite large, in estimation. In the present study, we used six harmonics, which was quite high to estimate soil heat flux for every 24-hour period. In addition, the coefficients in Equation (19) need to be estimated using the Fourier series analysis. The errors in the coefficients can also result in the errors in the estimation. Overall, the combined effects may produce large errors in estimated soil heat flux. An indirect evidence was that there existed a difference between the interpolated temperature and the temperature using the harmonic expression (Equation (14)) by $-0.2 \pm$

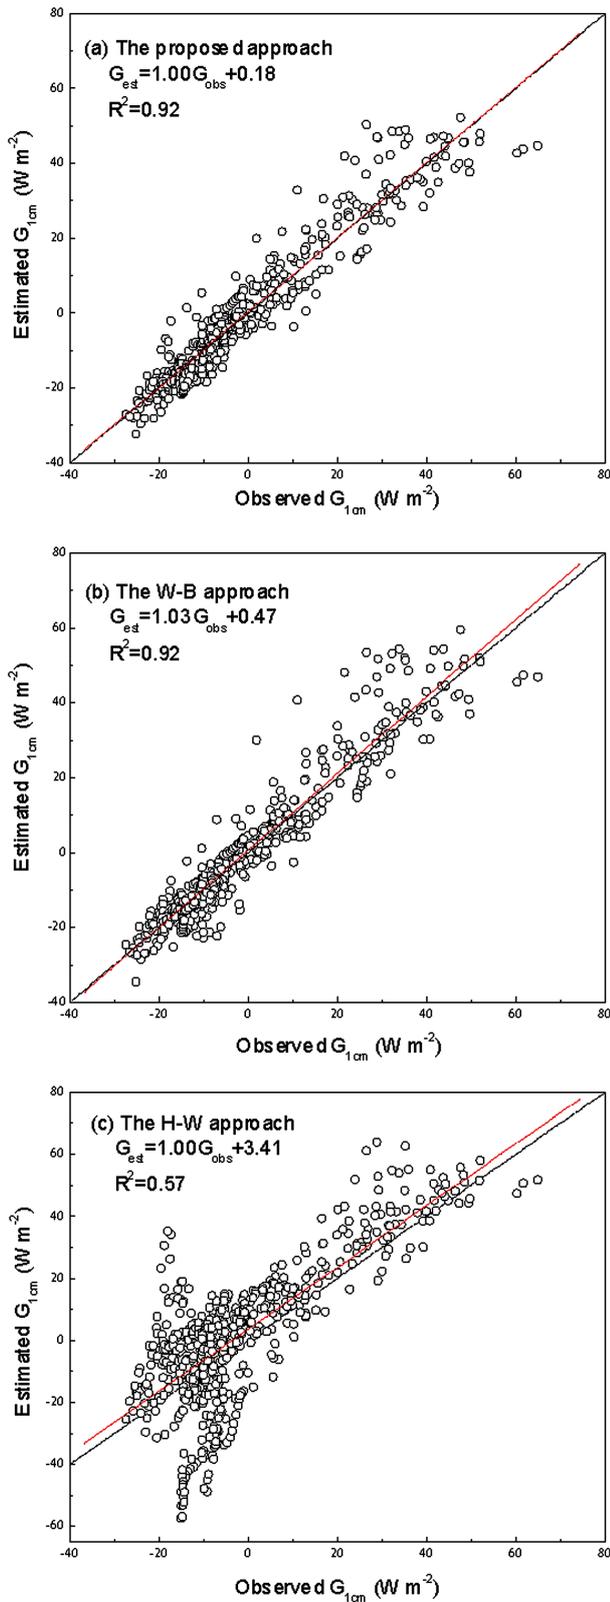

Figure 5. Comparison of observed soil heat flux against estimated values from the generalized approach (a), the W-B approach (b), and the H-W approach (c) at a depth of 1-cm at Shouxian of China.

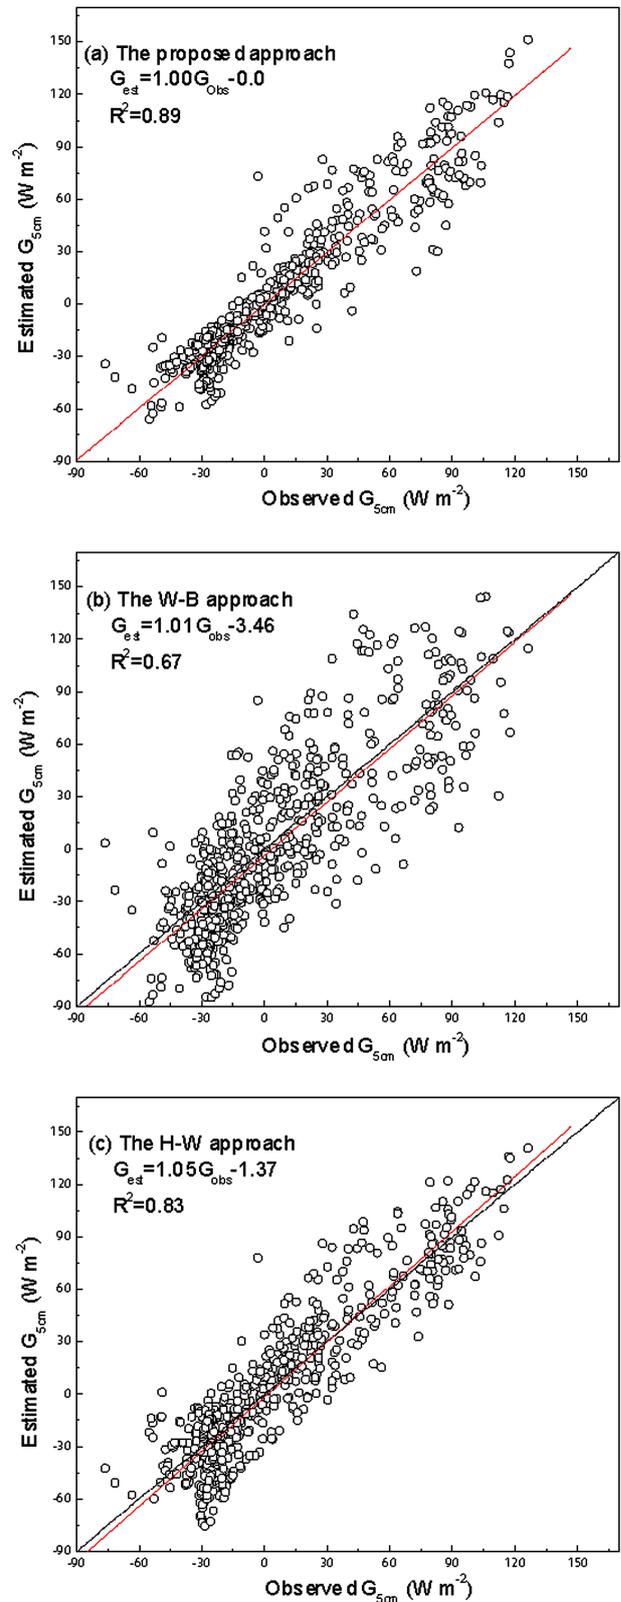

Figure 6. Comparison of observed soil heat flux against estimated values from the generalized approach (a), the W-B approach (b), and the H-W approach (c) at a depth of 5-cm at Changwu of China.

Table 1. Statistical differences between the observed soil heat flux against the estimated values from the generalized approach, the W-B approach and the H-W approach at Shouxian and Changwu of China.

		The generalized approach	The W-B approach	The H-W approach
	R^2	0.92	0.92	0.57
Shouxian (N = 680)	Mean	0.17	0.39	1.80
	S.D.	4.9	5.1	14.2
	RMSE	4.9	5.2	14.6
	R^2	0.89	0.67	0.83
Changwu (N = 720)	Mean	0.00	-3.33	-1.3
	S.D.	13.4	27.5	18.5
	RMSE	13.3	27.7	18.7

0.7°C on average at a depth of 1 cm at Shouxian. The difference generated the discrepancy between the soil heat fluxes estimated from the W-B approach and the H-W approach by $-3.0 \pm 13.4 \text{ W}\cdot\text{m}^{-2}$. **Figure 8** illustrated the statistical relationship between the tempera-

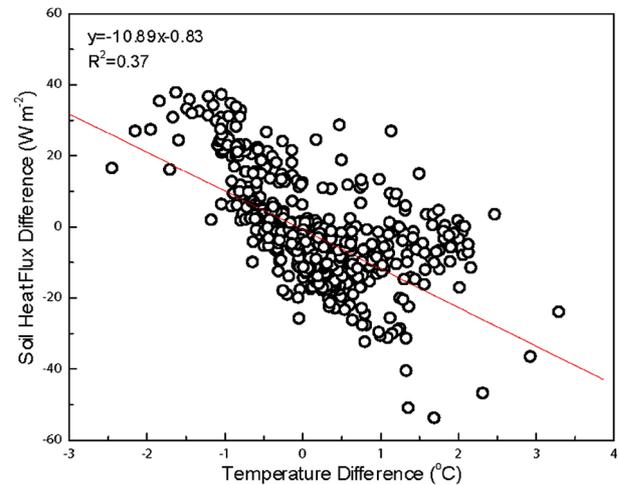

Figure 8. Statistical relationships between the temperature difference and the soil heat flux difference at a depth of 1-cm at Shouxian of China. The temperature difference refers to the difference between the values calculated from the cubic-spline interpolation approach and that from the harmonic equation (Equation (14)). The soil heat flux difference refers to the difference between the values estimated by the W-B approach and by the H-W approach.

ture difference and the soil heat flux discrepancy. One degree temperature difference could produce approximate $10 \text{ W}\cdot\text{m}^{-2}$ at the site. Therefore, use of the cubic-spline interpolation should be with caution to obtain inner soil temperature for the H-W approach.

In general, all these approaches can be used for estimating soil heat flux using single-layer data. The generalized approach is superior to the W-B approach and the H-W approach in that it has less restrictions and assumptions but higher overall accuracy. The approach can estimate soil heat flux at any depth but it requires only surface temperature data as input, which appears to be an advantage to remote sensing applications. Even errors in temperature measure make limited effects on soil heat flux estimates, yet it faces difficulty when applied to satellite remote sensing. One of the difficulties is that it is difficult for remote sensing to accurately estimate K , C_s , or a . While the present study is validated at in situ scale, further extensive investigation is necessary for expanding its application to large scale.

5. Conclusions

The Duhamel's theorem was used to derive Equation (11) for estimating soil heat flux at any depth solely from time series of surface temperature measurements. This equation can be extended to estimate soil heat flux below a given depth if soil temperature at that depth is known. The W-B approach is a derivative form of the generalized approach. With temperature expressed with harmonic equation, we also derived the H-W approach from the

generalized approach. Of all these approaches, the generalized approach offers a way with less restriction and assumptions to estimate soil heat flux.

Error analysis revealed that measurement errors in surface temperature would have limited effects on soil heat flux estimates from the generalized approach. Model simulation showed that soil heat flux estimated from the generalized approach agreed quite well with the simulated from heat transfer equation. Furthermore, case examinations demonstrated that it achieved best performance at two observation sites with contrasting climate regimes. The W-B approach achieved better results at Shouxian, and the H-W approach did better at Changwu. The error sources were related to the assumptions and estimation errors in the coefficients used in each approach. In general, Equation (11) was recommended for practical use in estimating soil heat flux. Further investigation is necessary if the approach is applied at a large scale.

Acknowledgements

This work was jointly supported by a Key Program of Nanjing Institute of Geography and Limnology, Chinese Academy of Sciences (CAS) (NIGLAS2012135001) and the CAS 100-talent Project. We thank Dr H Tanaka for his kind assistance in data acquisition and his valuable comments to improve the early manuscript.
