ABSTRACT

In this study investigation of influence of hybrid nanosilica-polyethylene glycols materials (molecular weight 1500, 6000 and 15000), prepared by sol-gel synthesis, on lipid peroxidation and antioxidant activity of human serum in vitro was performed. Methods included chemiluminescence analysis and quantitative malonic dialdehyde estimation. It was revealed that nanosilica-PEG materials with different molecular weight had certain biological activity. Powders of SiO₂-PEG 1500 and SiO₂-PEG 6000 manifest prooxidant effects, whereas mesoporous (calcine) powders produced antioxidant effects in blood serum in vitro.

Keywords: Free-Radical Oxidation, Nanosilica, Chemiluminescence, Malonic Dialdehyde

1. Introduction

The study of free-radical processes of lipid oxidation and antioxidant system is an important problem of modern biomedicine. Oxygen is a powerful oxidant and oxygen-mediated reactions are the main sources of energy for variety of biological species. Metabolic processes produce reactive oxygen species (ROSs), free radicals, peroxides, malonic dialdehyde, Schiff's bases, which damage membrane structures and lead to oxidative stress, being the causative factor for a lot of widely spread diseases, including reproductive disorders and prenatal injuries [1-3].

Concerning this the role of antioxidants is to neutralize toxic products of free-radical lipid peroxidation. In conditions of excessive peroxidation the capacity of antioxidant defense may decrease due to insufficient endogenous antioxidant production or unfavorable environment factors [3]. Various substances are known to have antioxidant activity; their investigation is of certain importance for both biology and medicine [4].

Nowadays silica compounds attract considerable attention. Silica stimulates fibroblastic activity of mesenchyma, promoting granulation and scarring. The lack of

silica may lead to depression of leukocyte activity in inflammation, poor wound scarring, anorexia, pruritus, tissue flexibility decrease, skin turgor decrease, vascular permeability increase and haemorrhagia as a result. Apart from this silica antioxidant activity stands [5].

Investigators of peroxidation showed that silica powders stimulated active oxygen species and free radicals production in culture of epithelial cells, resulting in caspase activation and apoptosis [6]. Some authors experimentally found out that inhalation of crystalloid silica in animals lead to oxidative stress, inflammation and alveolar fibrosis [7,8].

As a catalysts and functional composite materials special attention is attracted by matrix hybrid silica derivates. In this study we presented physical-chemical properties of silica-based materials and their influence on peroxidation processes in human serum. Silica nanoparticles are biologically inert, have high adsorption rate, thermal and mechanic stability, and therefore are expected to manifest antioxidant activity.

The aim of the work was to study the influence of organic-inorganic silica and polyethylene glycols compounds on free-radical processes *in vitro*.

2. Materials and Methods

2.1. Reagents for Silica Nanoparticles Synthesis

Tetraethoxysilane (TEOS) ($C_2H_5O)_4Si$ (high purity grade, Ekos-1, Russia), diethylamine ($C_2H_5)_2NH$ (moderate purity grade, Aldrich), polyethylene glycols [-OCH₂CH₂-]_n with molecular weight of 1500, 6000, 15000 (Aldrich) and rectified ethanol (96 wt%) were used without further purification.

2.2. Synthesis of Hybrid Organic-Inorganic SiO₂-Polyethylene Glycol Materials

The synthesis was carried out in ethanol media at temperature of 20°C. Polyethylene glycol was dissolved in required amount of water and was added to ethanol. Than a catalyst of tetraethoxysilane hydrolysis – diethyl amine – was added. The resulting mixture was homogenized for 15 min. After that small doses of tetraethoxysilane (0.5-1.0 ml) were injected into the system using syringe. Total synthesis time was 17 hrs. Particles were filtered from the original solution and dried out on open air at temperature of 70-100°C until mass stability.

We investigated two types of hybrid organic-inorganic SiO₂-PEG materials: noncalcine and calcine in muffle furnace (800°C, 2 hrs).

2.3. IR Spectroscopy

IR spectra of produced powders were recorded using Avatar 360 FT-IR ESP spectrometer (wave range: 400-4000 cm⁻¹). Preliminary samples of powders were grinded with KBr in agate mortar and pressed in discs.

2.4. Thermogravimetry

Thermogravimetric measuring were performed on thermoanalytical installation. The mass of a sample was 80-90 mg. The heating was carried out from room temperature up to 1000°C with rate of 5°C per min.

2.5. Brunauer-Emmett-Teller (BET) Surface Area Measurement

First step of BET analysis was heating of samples to eliminate adsorbed impurities. Then argon at temperature of 77K was adsorbed on materials to form a monomolecular film on accessible area. The amount of adsorbed argon served to determine the BET surface area.

In experiments we used native serum of 10 patients, administered in obstetrical or gynecological clinics of Ivanovo Research Institute of Maternity and Childhood. We decided not to use whole blood to prevent coagulation. Suspension of studied powders was added to 1 ml of native serum, which was then incubated at 4°C for 1 hr.

The ratio between powders and serum was 5.0 g/L for mesostructured (noncalcine) powder and 50.0 g/L for mesoporous (calcine) powder. At this stage of experiments we didn't try to evaluate pharmacological doses of studied powders as the only aim of experiments was to determine any possible pro- or antioxidant properties of synthesized materials *in vitro*. The incubation temperature was found to limit bacterial activity. Native serum without nanomaterials stood for control. After incubation samples were centrifuged at 3000 rpm for 10 min. Supernatants were transferred into clean dry tubes and underwent analysis.

2.6. Estimation of Peroxidation Intensity by Induced Chemiluminescence (CL)

The method was based on catalytic reduction of peroxides by bivalent ferric ions. Generated free radicals acted as oxidation initiators in biological substrate. Free radicals recombination followed by photon release, which could be registered in 40 s. This was a period of maximal intensity. We used hydrogen peroxide and ferric sulfate as biochemiluminescence inductors. 0.1 ml of serum was mixed with 0.4 ml phosphate buffer (pH 7.5), 0.4 ml ferric sulfate (0.01 mM), 0.2 ml 2% hydrogen peroxide and underwent CL. Intensity of luminescence was evaluated by BHL-06M biochemiluminometer (Russia). Registered parameters were as follows (Figure 1): peak intensity (I_{max}) – the highest intensity of luminescence registered within first 40 seconds of Fenton's reaction; light sum (S) – the area under the curve of luminescent signal; slope of the curve ($\tg \alpha$) – tangent of decrease signal angle.

I_{max} and S reflected potential for lipid peroxidation. Antioxidant activity was characterized by $\tg \alpha$ and coefficient K (I_{max}/S ratio).

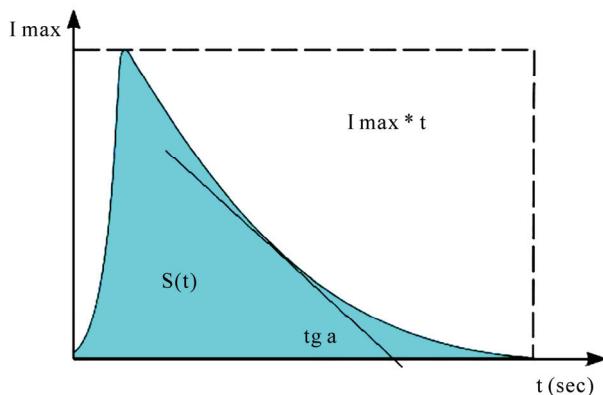

Figure 1. Typical kinetics of serum chemiluminescence. The registered parameters are as follows: peak intensity (I_{max}), light sum ($S(t)$), the slope of the curve ($\tg \alpha$).

2.7. Malonic Dialdehyde Serum Concentration Measurement

The method was based on reaction between malonic dialdehyde (MDA) and thiobarbituric acid [9]; the product of reaction had pink color and was identified by SF-46 spectrophotometer (Russia) on wave length 523 nm.

3. Results and Discussion

Qualitative and quantitative structure of materials was investigated by IR spectroscopy and thermogravimetric analysis.

Thermograms of hybrid organic-inorganic SiO₂-PEG material (molecular weight 15000) are presented on **Figure 2**.

Burning of polymer component from matrix SiO₂-PEG 15000 hybrid is described by the peak with maximum at 291°C on differential thermogravimetric diagram. The amount of organic phase was 39 wt% in sample. Water content was 13.5 wt%. The curve of differential thermal analysis did not reveal any thermal effects.

Figure 3 shows IR spectra of hybrid organic-inorganic (a) SiO₂-PEG 15000 and (b) material calcined at 800°C.

There were characteristic oscillations of Si-OH and Si-O-Si found in spectra. Also, in areas of wavenumbers 3600-3500, 1640 and 400-200 cm⁻¹ oscillations of adsorbed H₂O, isolated and linked OH groups were found.

In spectrum of hybrid organic-inorganic SiO₂-PEG 15000 oscillations of alkyl CH₃, CH₂ and CH groups [10-19] proved the presence of organic phase in composite.

Intensive flat halo on X-ray diagram of hybrid SiO₂-PEG 15000 material reflected its amorphism (**Figure 4**).

Results of sedimentation gave data on morphology of hybrid material powders. Sizes of particles of hybrid SiO₂-PEG composite determined by sedimentation before and after calcining were (**Figure 5**) as follows. Hybrid material: 2-300 µm, with the prevalence of 24 and 150 µm fractions; tempered material: 2-110 µm, with modal size 28 µm. Specific areas of noncalcine and calcine hybrid organic-inorganic SiO₂-PEG 15000 material powders were discovered by thermal desorption of argon (**Table 1**).

Thus, there were synthesized two groups of composite materials with different structure: organic-inorganic compounds with amorphous structure and mesostructural materials with system of ordered mesochannels, filled by molecular organic templates. All materials were calcined at 800°C for creating of high-porous silica specimens with the same structural features as their noncalcine ancestors. Investigation of pro- and antioxidant properties

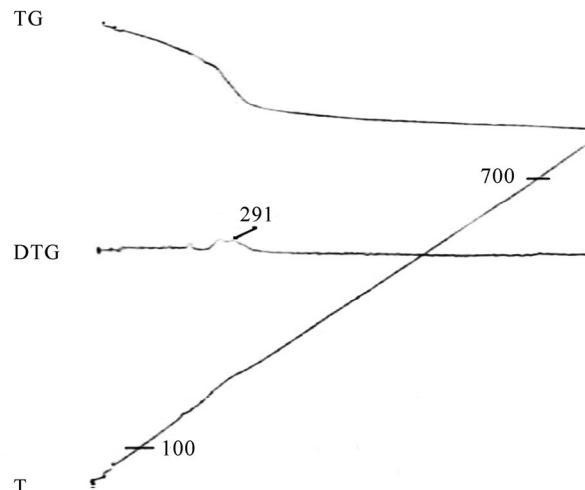

Figure 2. Thermograms of hybrid organic-inorganic SiO₂-PEG 15000 material.

Table 1. Specific surface areas of hybrid SiO₂-PEG 15000 and calcined at 800°C materials.

Material	Specific surface area by BET, m ² /g
SiO ₂ -PEG 15000 (noncalcine)	91
SiO ₂ -PEG 15000 (calcine)	> 800

of these powders was carried out *in vitro*.

Biochemical study revealed different influence of investigated powders on intensity of peroxidation in human serum (**Tables 2** and **3**). Parameters of chemiluminescence revealed in native serum were estimated as 100%.

Adding of SiO₂-PEG powders with molecular weight 1500 and 6000 to experimental system lead to increased chemiluminescence, which proved high ROS and free radical (R-, OH-, RO-, RO₂-, O₂-) production in Fenton's reaction [20,21]. Recombination of radicals formed unstable tetraoxide, which disintegrated with photon emission and raised lightsum S (plus 23%, p = 0.0081 and 18%, p = 0.0131, comparing with controls, respectively for 1500 and 6000 powders), fast flash I_{max} (plus 26%, p = 0.0459 for 1500 powder). Investigation of SiO₂-PEG with molecular weight 15000 didn't reveal any significant CL changes. Study of mesoporous (calcine) SiO₂-PEG powder revealed its antioxidant activity, which was developed by decreasing of peroxidation processes intensity in Samples 3 and 5 (**Table 3**). We found increasing of tg α (plus 15%, p = 0.0510) and decreasing of MDA. The conclusion was that nanosilica-PEG compounds with different molecular weight possessed specific oxidant and antioxidant activity. SiO₂-PEG 1500 and SiO₂-PEG 6000 powders lead to activation of free-radical oxidation,

Note: Numbers 1, 2, 3, 4, 5, 6 stands for different preparations of mesoporous (calcine) SiO_2 -PEG with different molecular weight (1500, 6000, 15000).

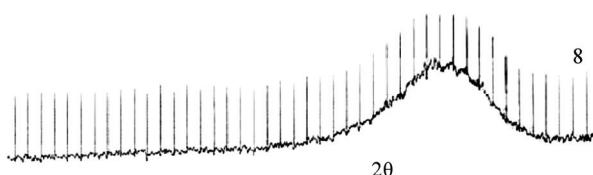

Figure 4. X-ray diagram of hybrid organic-inorganic SiO_2 -PEG 15000 material.

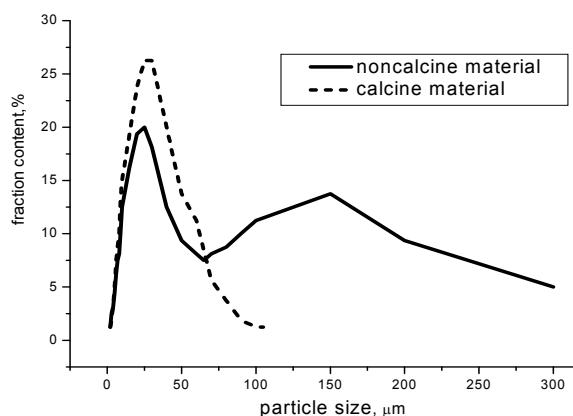

Figure 5. Particle size distribution in noncalcine and calcine hybrid organic-inorganic SiO_2 -PEG 15000 materials.

whereas mesoporous (calcine) materials with molecular mass 6000 and 15000 manifested antioxidant properties in human serum due to their large specific surface area ($> 800 \text{ m}^2/\text{g}$). These findings can be useful for creating of pharmacological preparations.
