## Abstract

We report herein a case of a 40-year-old male patient with chronic renal failure presenting a severe hyperparathyroidism with an elevation of parathormone level evaluated in nuclear medicine department for MIBI-Techne-99m parathyroid scintigraphy. The parathyroid scintigraphy revealed the appearance of a preferential fixation of the MIBI-99mTc opposite the lower left pole of the thyroid and opposite the upper part of the right hemi thorax. A subsequent single-photon emission computed tomography-computed tomography focused on the cervico-thoracic region was performed and showed an ectopic parathyroid adenoma associated with an incidental brown tumor mimicking bone and lung metastases. Our case report confirms the usefulness of additional hybrid SPECT-CT imaging in the management of hyperparathyroidism.

## Keywords

Hyperparathyroidism, Thyroid Scintigraphy, Parathyroid Scintigraphy, Technetium-99m, MIBI-Techne-99m, SPECT/CT, Ectopic Parathyroid Adenoma, Brown Tumor

## 1. Introduction

Brown tumors are rare osteolytic bone lesions found in 4.5% of patients with primary hyperparathyroidism (PHPT) and 1.5% to 1.7% of patients with secondary hyperparathyroidism (SHPT). They can affect the entire skeleton and the most common locations are the pelvis, ribs, mandible and hands. Localizations on the long bones are extremely rare. Brown tumors are involved in osteolytic

bone lesions that can mimic malignant bone tumors [1]. We report herein the case of a patient referred for isotopic exploration looking for a parathyroid adenoma in a context of secondary hyperparathyroidism in which the parathyroid scintigraphy and the complement by SPECT/CT scan allowed to highlight an associated ectopic parathyroid adenoma with a brown tumor mimicking bone and lung metastases thus allowing to provide best care for this patient after an accurate diagnosis.

## 2. Patient and Method

This is a 40-year-old male patient with a story of a chronic smoking cessation and chronic hemodialysis for 5 years, referred to the Nuclear Medicine department for an isotopic exploration of a secondary hyperparathyroidism (SHPT) with a biological assessment revealing a normal calcemia at 2.3 mmol/L (Normal value: 2.2 - 2.6 mmol/L) and a parathormone level raised to 3226.6 pg/mL (Normal value: 15 - 88) in favor of secondary hyperparathyroidism. The parathyroid scintigraphy was carried out in two stages according to a hybrid wash-out protocol (double tracer) with acquisition of images on a hybrid gamma camera dual head SPECT/CT Siemens Symbia T6 2010. The first step consisted in a thyroid scintigraphy with the creation of a planar recording in previous incidence 10 min after injection of 50 MBq of Pertechnetate. Then the second stage consisted in the realization of a parathyroid scintigraphy by a planar recording in anterior incidence 10 min then 2 hours and 4 hours after injection of 550 MBq of MIBI-99mTc followed by a tomoscintigraphy coupled with a single-photon emission computed tomography-computed tomography (SPECT/CT) scan examination [2] [3].

## 3. Results

The 99mTc thyroid scintigraphy made it possible to visualize a thyroid gland in a normal anatomical position and suitable fixation. While the MIBI-99mTc parathyroid scintigraphy made it possible to highlight on the early image and the late images compared to the thyroid image with 99mTc the appearance of a preferential fixation of the MIBI-99mTc opposite the lower left pole of the thyroid and opposite the upper part of the right hemi thorax (**Figure 1**) better visible on the subtraction image (**Figure 2**). Parathyroid Scintigraphy with MIBI-99mTc combined with the SPECT/CT scan performed 4 hours later after a cervico-mediastinal centering revealed an ectopic parathyroid adenoma behind the left sterno-clavicular joint. (**Figure 3**) and an osteolytic bone lesion of the 4th right rib blowing the cortex, expansive and extended to the adjacent pulmonary field (**Figure 4**) suggesting a brown tumor in this context.

## 4. Discussion

SHPT is the most common cause of benign hypercalcaemia and is linked in 85% of cases to a parathyroid adenoma. The main pathogenic mechanism leading to

**Figure 1.** Thyroid Scintigraphy with  $^{99m}\text{Tc}$  then with MIBI- $^{99m}\text{Tc}$  in anterior cervico-thoracic incidence performed 10 min, 2 hours and 4 hours after an IV injection of 550 MBq of MIBI- $^{99m}\text{Tc}$ .

**Figure 2.** Subtraction image showing a focal point of preferential accumulation of MIBI- $^{99m}\text{Tc}$  projecting opposite the lower left pole of the thyroid and a second focal point facing the upper part of the right chest.

SHPT is a deficiency of 1,25-dihydroxycholecalciferol, which results in hypocalcaemia and hyperphosphatemia, leading to an increase in the production and secretion of PTH by the parathyroid gland. In 1934, Albright made the first description at the level of the facial skeleton of a Brown tumor. Brown tumors are an extreme form of manifestation of fibrocystic osteitis. The tumor lesion

**Figure 3.** SPECT/CT showing an ectopic parathyroid adenoma behind the left sternoclavicular joint.

**Figure 4.** SPECT/CT showing an osteolytic bone lesion of the 4th right rib blowing the cortex, expansive and extended to the adjacent pulmonary field.

corresponds to trabecular resorption phenomena complicated by micro fractures with intra-lacunar bleeding. These are very vascular lesions which may contain necrotic centers and hemosiderin deposits, hence the characteristic brown color [4]. The reported prevalence of brown tumors has decreased to <0.1%. Due

to the quality of medical care and screening in developed countries, it is increasingly rare to find an associated bone disease in secondary hyperparathyroidism. There have been reports of extensive multiple brown tumors, some of which mimic cancer metastases, due to hyperparathyroidism due to a parathyroid adenoma [5] [6] [7]. According to a review of the recent literature there are only a few reported cases of brown tumors caused by parathyroid carcinoma [5]—two cases of mandibular brown tumors and two cases of multiple brown tumors in the lower limbs [7] [9]. Symptoms related to brown tumors depend on their size, location and the nature of the adjacent structures. Bone pain, fractures and neurological deficit have been described [8] [9]. These lesions and associated symptoms usually regress after correction of hyperparathyroidism.

Parathyroid Scintigraphy is a localization examination. It should not be used to make the positive diagnosis of hyperparathyroidism, which is essentially biological. Its level of indication is variable depending on the clinical situation. MIBI labeled with  $^{99m}\text{Tc}$  is a cationic and lipophilic molecule which once captured, concentrates in the mitochondria of thyroid and parathyroid cells. As the parathyroid adenomatous cells are particularly rich in mitochondria, they will capture radio pharmaceutical sequestration longer than in the thyroid [2], the Parathyroid Scintigraphy with  $^{99m}\text{Tc}$ -MIBI therefore has good sensitivity for the detection of parathyroid adenomas. A positive scan is correlated with the size of the adenoma and the levels of ionized calcium. The procedure may include a hybrid SPECT/CT scan acquisition, which is useful for locating the pathological parathyroid gland and identifying ectopic adenomas [2]. This precise location is useful for performing a minimally invasive parathyroidectomy.

The absorption of MIBI in brown tumors and bone metastases has also been described [5]. In our case, while the MIBI- $^{99m}\text{Tc}$  Scintigraphy allowed us to visualize the abnormal cervical and thoracic absorption (**Figure 1** and **Figure 2**), SPECT/CT scan allowed us to localize a lower left parathyroid adenoma (**Figure 3**) and the osteolytic bone lesion of the 4th right rib extended to the right pulmonary field (**Figure 4**) evoking a brown tumor.

Multiple brown tumors without focal absorption of MIBI- $^{99m}\text{Tc}$  have also been described and are thought to be linked to a lack of mitochondria. In such cases,  $^{18}\text{F}$ -FDG PET/CT scan could allow the detection of these tumors [10].

The goals of preventing and treating brown tumors include the normalization of calcaemia and phosphoremia. A total or a subtotal parathyroidectomy is usually done to decrease serum PTH levels. Finally a lumpectomy could be performed in certain indications [6] [9].

In our case, the diagnosis of parathyroid adenoma and Brown's tumor were confirmed by a histological examination and the parathormone level decreased considerably to a suitable value after a surgery following a multidisciplinary management.

## 5. Conclusion

Apart from the rarity and originality of the reported clinical case, our study

highlights the key role of isotopic imaging procedures, in particular parathyroid Scintigraphy and SPECT/CT scan coupling in the exploration of hyperparathyroidism, by locating the ectopic parathyroid adenoma, diagnosing the brown tumor and defining its anatomical relationships, thus improving the management of hyperparathyroidism and allowing the medical team to anticipate an unusual situation.

### Conflicts of Interest

The authors declare that they have no conflicts of interest regarding the production of this article.

### Ethical Approval

Obtained by the ethics committee of the Faculty of Medicine and Pharmacy of Sidi Mohamed Ben Abdellah University of Fez.

### Consent to Publication

Obtained from the patient.

### Availability of Data and Material

Data sharing does not apply to this article because no data set was generated or analyzed during the current study.

## *What is SCIRP?*

Scientific Research Publishing (SCIRP) is one of the largest Open Access journal publishers. It is currently publishing more than 200 open access, online, peer-reviewed journals covering a wide range of academic disciplines. SCIRP serves the worldwide academic communities and contributes to the progress and application of science with its publication.

## *What is Open Access?*

All original research papers published by SCIRP are made freely and permanently accessible online immediately upon publication. To be able to provide open access journals, SCIRP defrays operation costs from authors and subscription charges only for its printed version. Open access publishing allows an immediate, worldwide, barrier-free, open access to the full text of research papers, which is in the best interests of the scientific community.

- High visibility for maximum global exposure with open access publishing model
- Rigorous peer review of research papers
- Prompt faster publication with less cost
- Guaranteed targeted, multidisciplinary audience
