## Abstract

Preventive Maintenance Programme consists of actions that improve the condition of system elements for performance optimization and aversion of unintended system failure or collapse. It involves inspection, servicing, repairing or replacing physical components of machineries, plant and equipment by following the prescribed schedule. It is commonly agreed nowadays that preventive maintenance programme can be very successful in improving equipment reliability while minimizing maintenance related costs. The availability of a complex system, such as steam turbine power plant is strongly associated with its parts reliability and maintenance policy. That policy not only has influence on the parts' repair time but also on the parts' reliability affecting the system integrity, degradation and availability. The objective of this paper is to study the effects of Preventive Maintenance Programme (PMP) implementation on the performance of the Egbin 1320 MW thermal power plant in Nigeria. This paper considers the reliability and availability of the  $6 \times 220$  MW steam turbine units installed in the power station. The reliability and availability of the turbines are computed based on a five-year failure database. The availability analysis of available data from 2005 to 2009 shows different results for each unit and variation in availability for different year: availability of unit1 varies between 59.11% to 91.76%; unit 2, 64.02% to 94.53%; unit 3, 28.79% to 91.57%; unit 4, 80.31% to 92.76% and unit 5, 73.38% to 87.76%. Unit 6 was out of service for the past 2 to 3 years. This indicates differences in their systems installation maintenance and operation.

**Keywords:** Preventive Maintenance Programme, Power Plant, Reliability, Availability, Turbine

## 1. Introduction

Preventive maintenance scheduling of generating units is an important task in a power plant and plays major role in operation and planning of the system. The economic operation of an electric utility system requires the simultaneous solution of all aspects of the operation scheduling problem in the face of system complexity, different time-scales involved, uncertainties of different order, and dimensionality of problems [1].

Today, preserving and/or enhancing system reliability and reducing operations and maintenance (O & M) costs are top priorities in utilities. As system equipment continue to age and gradually deteriorate the probability of service interruption due to component failure increases. An effective maintenance strategy is essential in delivering safe and reliable electric power to customers eco-

nomically [2].

All utilities perform maintenance of system equipment in order to supply electricity with a high reliability level. The reliability of system operation and production cost in an electric power system is highly affected by the maintenance outage of generating facilities. Optimized maintenance schedule could save millions of dollars and potentially defer some capital expenditure for new plants in times of tightening reserve margins, and allow critical maintenance work to be performed which might not otherwise be done. Therefore, maintenance scheduling for electric utilities system is a significant part of the overall operations scheduling problems.

Power plants components are able to remain in operating condition by regular preventive maintenance.

The purpose of maintenance scheduling is to find the sequence of scheduled outages of generating units over a

given period of time such that the level of the energy reserve is maintained [3].

In an increasingly competitive power delivery environment, electric utilities are forced to apply more proactive methods of utility asset management. One of the main components of electric power delivery asset management is the capital budgeting and O & M of existing facilities. Since in many cases the cost of construction and equipment purchases are fixed, O & M expenditure is the primary candidate for cost cutting and potential savings. As system equipment continue to age and gradually deteriorate the probability of service interruption due to component failure increases.

Electric utilities are confronted with many challenges in this new era of competition: rising O & M costs, growing demand on system, maintaining high levels of reliability and power quality, and managing equipment aging. Therefore, the health of equipment is of utmost importance to the industry because revenues are affected by the condition of equipment. When demand is high and equipment is in working order, substantial revenues can be realized. On the contrary, unhealthy equipment can result in service interruption, customer dissatisfaction, loss of good will, and eventual loss of customers. An effective maintenance strategy is essential to delivering safe and reliable electric power to customers economically [2].

The availability of a complex system, such as steam turbine power plant, is strongly associated with the parts reliability and the maintenance policy. That policy not only influences the sub-system and parts' repair time but also their reliability affecting the system degradation and availability. The maintenance policy philosophy is focused on the use of predictive or preventive maintenance tasks that aim at the reduction of unexpected failures during the component's normal operation [4,5].

In a large enterprise, such as a power plant, keeping asset reliability and availability, and reducing costs related to asset maintenance, repair and ultimate replacement are at the top of management concerns [6]. In response to these concerns, the Reliability Centered Maintenance (RCM) was developed by Stanley Nowlan and Howard Heap in 1978 [7]. RCM has been defined formally by Moubrey [8] as 'a process used to determine what must be done to ensure that any physical asset continues to do whatever its users want it to do in its present operating context'. For complex systems such as steam turbines, the occurrence of unexpected component failures drastically increases maintenance costs associated with corrective tasks not only for the direct corrective costs (spare parts, labour hours) but also for the system unavailability cost.

The maintenance policy aims to reduce the system

unavailability through the use of predictive or preventive maintenance tasks for critical components. This policy allows the reduction of unexpected failure occurrences that cause the system unavailability and are usually very expensive to repair.

In Nigeria, maintenance practices leave much to be desired. Maintenance is generally regarded in Nigeria as an undesirable cost generating activity rather than one resulting in improved reliability, greater profitability and higher productivity [9]. In Nigeria, maintenance is still too often neglected and so the resulting associated costs as a percentage of the total operational cost keep rising. The most notable problem is the absence of an effective and efficient maintenance strategy.

The investigation of Eti, *et al.* [10] showed that, maintenance cost, in the power industries in Nigeria amount to approximately 23 - 35 percent of the total production cost, that is much more than that for fuel.

The increasing electricity demand, the increasingly competitive environment and the recent deregulation of Nigeria's electricity supply sector are resulting in increased competition among the independent power producers. To survive, suppliers must reduce maintenance costs, prioritize maintenance actions and raise reliability.

Electric power projects in many countries, except Nigeria, are reliable; address specific customers' requirements, and environmental compliance.

Failures in electric power stations result in downtime, production losses and economic losses as well. Obviously, to achieve the global maintenance objective of realizing high machinery availability at minimum cost, adequate cognizance must be given to the element that make up the cost, *i.e.* the cost of machine unavailability and the cost of maintenance resources. Striking a balance between these two costs to achieve the minimum total cost creates an ideal maintenance situation. This should be the objective of a good maintenance plan [11]. The objective of this paper is to study on the effects of Preventive Maintenance Programme (PMP) implementation at Egbin 1320 MW thermal power plant in Nigeria. The paper aims to evaluate the reliability and availability of the 6 × 220 MW steam turbine units installed in the power station. The Egbin power plant is one of the largest base generating power plants of the public power company of Nigeria, the Power Holding Company of Nigeria (PHCN).

## 2. Energy Crises in Nigeria

The quality of life of the citizens of in any country is highly dependent on the availability of a reliable supply of power. According to Chigbue [12], power as a major component in the requirements for effective industrial-

zation and development is grossly inadequate in Nigeria.

For many years now, Nigeria has been facing an extreme electricity shortage. This deficiency is multi-faceted, with causes that are financial, structural, and socio-political, none of which are mutually exclusive [13]. At present, the power industry in Nigeria is beset by major difficulties in the core areas of operation: generation, transmission, distribution and marketing [14].

In spite of Nigeria's huge resource endowment in energy and enormous investment in the provision of energy infrastructure, the performance of the power sector has remained poor, in comparison with other developing economies [15]. This assertion was confirmed by a World Bank [16] assessment study conducted on energy development in Nigeria, which compared the performance of Nigeria's power sector with those of 20 other developing countries. The study reveals that the sector had the highest percentage of system losses at 33 - 41 percent; the lowest generating capacity factor 20 percent; the lowest average revenue at US\$ 1.56 kWh; the lowest rate of return at 8 per cent; and the longest average accounts receivable period of 15 months.

There is no doubt that expensive and unreliable power remains a major concern to all sectors of the economy in Nigeria: the industrial, commercial, and domestic sectors especially. Multiple and unpredictable power cuts, which have become a daily occurrence in Nigeria, often result in equipment malfunctioning, which make it difficult to produce goods and provide service efficiently. As a result of this fundamental problem, industrial enterprises have been compelled to install their own electricity generation and transmission equipment, thereby adding considerably to their operating and capital costs.

Enweze [17] has estimated that about 25% of the total investments in machinery and equipment by small firms, and about 10% by large firms, were on power infrastructure. Despite the attempts by some firms to supplement the power supply by PHCN, electricity demand by consumers, particularly domestic users has continues to increase.

Since inception of NEPA (renamed Power Holding Company of Nigeria, PHCN in year 2004), the authority has gradually increased its installed and generating capacity in an effort to meet the ever increasing demand. Nevertheless, majority of Nigerians have no access to electricity and the supply to those provided is not regular [18]. According to Energy Policy report, from 2003, it is estimated that the population connected to the grid system is short of power supply over 60% of the time. The electricity access in Nigeria is about 40% overall, although it is much higher in the urban areas while it much lower in the rural areas. On a fundamental level, there is simply not enough electricity generated to support the

entire population in Nigeria.

### 3. Power Industry in Nigeria: Present State

The power sector is a critical infrastructure needed for the economic, industrial, technological and social development of Nigeria. Electricity consumption has become one of the indices for measuring the standard of living of a country. In Nigeria, power sector is presently being managed by the Power Holding Company of Nigeria (PHCN) as a vertically integrated utility comprising generation, transmission and distribution segments.

The national electricity grid presently consists of fourteen generating stations (3 hydro and 11 thermal) with a total installed capacity of about 8351.4 MW as shown in **Table 1**. The Transmission network is made up of 5000 km of 330 kv lines, 6000 km of 132 kV lines, 23 of 330/132 kV substations, with a combined capacity of 6000 MVA or 4600 MVA at a utilization factor of 80%. In turn, the 91 of 132/33 kV substations have a combined capacity of 7800 MVA or 5800 MVA at a utilization factor of 75%. The Distribution sector is comprised of 23,753 km of 33 kV lines, 19,226 km of 11 kV lines, 679 of 33/11 kV substations. There are also 1790 distribution transformer and 680 injection substations [19].

Although the installed capacity of the existing power stations is 8351.4 MW, the maximum load ever achieved was little above 4000 MW. Some of the power stations generate less than 45% of their installed capacities. By May, 2009 the average, generating capacity was about 2800 MW daily owing to corruption, political, grossly inadequate funding and mismanagement reasons [20]. Currently, most of the generating units have broken down due to limited available resources to carry out the needed level of maintenance. Hence, the electricity network has been characterized by constant system collapses as a result of low generating capacity by the few generating stations presently in service.

Repositioning of the power sector is a key stimulus to the rapid industrialization of all key sectors of the economy like manufacturing, telecommunications etc. As it can be seen in **Table 1**, the existing plants operate at far below their installed capacity as many of them have units that need to be rehabilitated, retrofitted and upgraded [21]. The percentage of generation capability from hydro is 34.89%, from gas turbine 35.27% and from steam turbine is 29.84%. The relative contributions of hydro power stations from energy (MWh) standpoint are higher than that of thermal power stations as opposed to installed power (MW) standpoint.

Some of the reasons adduced for low power availability include: gas pipelines vandalization resulting to inadequate gas supply by Nigerian Gas Company to most

**Table 1. Summary of generation capabilities of PHCN power stations as operated in the year 2008 (Jan-Dec).**

Plant	Operator	Age (Year)	Type	Installed Capacity (MW)	Average Availability (MW)	Availability Factor	No of Units installed	Current No Available

thermal power plants, aged plants, outdated equipment (generators, turbines, governors, transformers, and switch gears). In addition to these, the transmission network is radial and overloaded, and suffers from the following constraints [20]:

- Cannot wheel more than 4000 MW;
- Has poor voltage profile in most of the network, especially in the North;
- Inadequate dispatch and control infrastructure;
- Radial and fragile grid;
- Frequent system collapses
- Higher transmission losses of 10% - 15%;
- Limited national access to electricity of about 40% for households, made up of 81% urban and 18% rural respectively.

Some of these constraints might be reduced or removed by replacing many of the transformers, strengthening the transmission and distribution systems and upgrading the switchgear.

For the past two decades, the power demand in Nigeria has been on the increase while available generating capacity remained largely static or even showing a decreasing long-term trend. The consequence of this was to load shed in order to ensure system stability (maintain equilibrium between available generation and selective demand).

The International Energy Institute's comparative analysis of the per capita consumption of electricity worldwide (**Table 2**), underscores the stark reality of Nigeria's power sector. The comparative analysis shows poor state of Nigeria's power sector, compared with even

some of the countries that began as newly independent countries in the 1960s. The challenge now is how reliable power supply can become accessible to majority of Nigerians at an affordable price.

Manufacturers Association of Nigeria (MAN) gave the following Comparative performance indicators shown in **Table 3**. The data for some Southern Africa Development Community (SADC) countries such as Botswana and South Africa are comparable to those of USA and France. The performance of the Nigerian power sector on the International Best Practices comparative rating is disgraceful cause for great concern. Perhaps, no other sector feels it as much as the manufacturing/ industrial sector wherein some notable international companies and organizations are on self-generated electricity on 24 hours daily for the 365 days of each year, as confirmed by a 2001 UNIDO. *Survey showed that manufacturers generated about 72% of total power required to run their factories on the average.*

The PHCN feeder reliability is extremely poor, with figures like 120 faults per kilometer per year compared to international best practice of 10 to 20.

#### 4. Maintenance Problems in Nigeria Electric Power Stations

Maintenance can be defined as all actions appropriate for retaining an item/equipment in, or restoring it to a given condition. More specifically, maintenance is used to repair broken equipments, preserve equipment conditions and prevent their failure, which ultimately reduces pro-

duction loss and down time as well as the environmental and associated safety hazards [22].

Maintenance activities in the Nigerian electric power industry are at present largely reactive, *i.e.* 'fire-fighting', to solve the problem, whatever it is, as quickly as possible and being in a state of readiness to deal with the next outbreak whenever it happens. The problems are expected but not prevented. Indeed, the view within this maintenance culture is that problems occur due to factors beyond practical and resource control: It is accepted that something will always go wrong and nothing much can be done about it in advance. The occurrence of the problem is often coupled with reactive responses—once the failures occur, the "fire-fighting" team is brought into action. However, because little is done in such a culture to anticipate problems or seek long-term solutions, the whole exercise becomes repeated far more often than it should be. Also, because the effort and resource go into

fire-fighting rather than prevention, faults occur. The basic approach would be different in a culture of long-term and continual improvement [9]. Comparisons have been made of modern maintenance practices in the more developed economics with that occurs in Nigeria. Significant differences arise due to variations in corporate culture, pertinent learning opportunities and effectiveness of strategic planning.

Efforts made by the Federal Government to improve availability and reliability of the electric power supplies in Nigeria have been frustrated by a lack of a corporate culture in all facets of management in Nigeria. Achieving the implementation of proactive maintenance, in any Nigerian organization, requires a cultural transformation. Commitment of the concerned individuals, a supportive cultural environment and wise leadership are fundamental prerequisites for achieving high quality maintenance. The training, fostering and competence building of the

managers themselves are crucial to a successful overall quality maintenance programme.

Maintenance management in Nigeria still esteems tough, individualistic, dominating leadership that often fails to perceive threats or opportunities. More effective management would be pivotal to organizing personnel to recognize pertinent opportunities and achieve worthwhile results rather than generate impasses, stagnation, bureaucracy and wasteful interpersonal friction.

The following maintenance problems are frequently encountered in Nigerian electric power stations:

- Maintenance is not treated seriously at board level, or even by local management;
- Maintenance processes lack a business culture (e.g. no business plans, ineffective or superficial budgets and unfocused reports);
- Maintenance technicians and even team leaders lack adequate management skills;
- Pre-occupation with introducing advanced maintenance methods, while relevant basic maintenance practices are not being implemented.

The Nigerian electric power industry still uses traditional maintenance planning to compile maintenance schedules for all equipment and plant. These schedules only rarely reach the shop floor. Hence, maintenance schedule ends up not being implemented.

### 5. Plant Condition and Maintenance Attitude in Egbin Power Station

Egbin power plant is the largest generating plant in Nigeria and one of the largest in West African Sub-region. The plant is located at the suburb of Lagos State, Ijede area of Ikorodu. The plant was commissioned in 1985 and consists of 6 units of 220 (6 × 220 MW) (Reheat-Regenerative). They are dual fired (gas and heavy oil) system with modern control equipment, single reheat; six stages regenerative feed heating. The overall cost of the plant was US \$ 1 billion with an expected life of 25 years. The estimated life was based on the fact that the plant should run mainly on natural gas which does not give the serious boiler slag and ash problem characteristic of coal fuel [23].

Natural gas is supplied to the plant directly from the Nigerian Gas Company (NGC), Lagos operations department, Egbin gas station, which is annexed to the thermal plant. Since Egbin thermal plant is located on the shores of the lagoon cooling water for the plant's condensers is pumped from the lagoon into the water treatment plant en route to the condensers. The station has been generating power far below installed capacity due to maintenance problems. These problems have affected the availability and reliability of the plant. **Figure 1** and

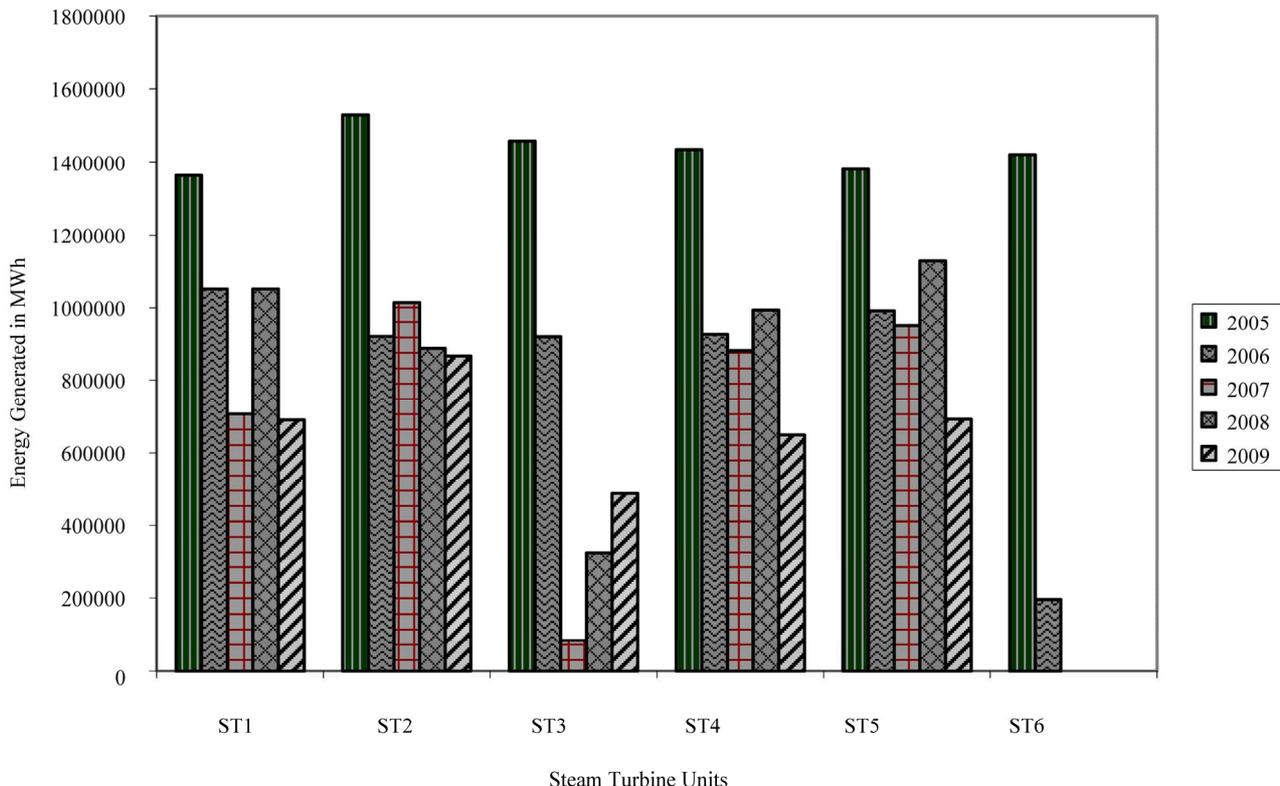

Figure 1. Unit by unit energy generation in MWh.

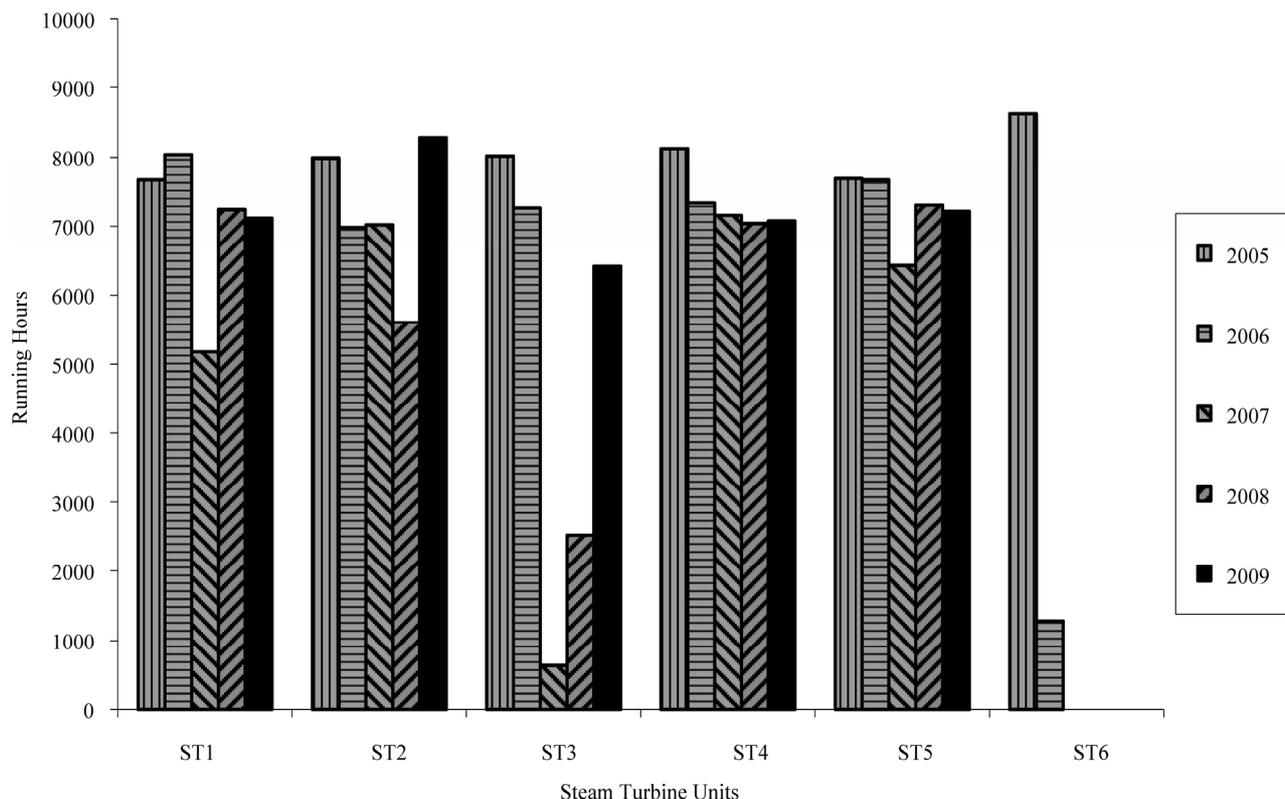

**Figure 2** show the energy generated and running hours of the plant from 2005 to 2009 respectively. The total energy generated from 2005 to 2009 varies from 3,383,869 to 8,591,905 MWh, while the running hours vary from 29,706.12 to 48,114.18 hrs. The highest total energy generated of 8,591,905 MWh was obtained in 2005, and the highest running hours of the plant also occurred in 2005. There has been a sharp declination in total energy generation and running hours from 2005 to 2009. In order to improve the plant performance and to minimize maintenance problems, there is need for effective maintenance scheduling which is a major determinant of the productivity of the workforce.

From a recent survey, there is evidence that the power station performs disappointingly compared with world-class operations [24]. There is frequent occurrence of breakdown of critical equipment. Also, overhauling operation is not always carrying out as schedule due to delay in release of fund. Turning around maintenance (TAM) is not done regularly due to politics. Apart from politics, due to small spare capacity available from gas turbine plant (24 MW) and emergency diesel generator (1.5 MW) which is not enough to be sent out, there is always fear of power outage. This is because during annual inspection, the plant has to be shut down for 30 or 40 days.

## 6. Results

**Table 4** shows the data on units' failures per year beginning from the year 2005 to 2009 at Egbin thermal power plant. Meanwhile, **Table 5** shows the data on units' outages duration for the past five years. The types of faults in the power plant can be categorized into 4 main groups: plant fault, system fault, gas fault and operational fault. **Figure 3** shows the total number of failures in hours according to the 4-main categories of faults from the year 2005 to 2009. Meanwhile, **Figure 4** shows the total number of overall time of plant outages in hours for all the functional units. From **Figure 1**, the most occurring fault is the plant fault. This is followed by gas fault. The highest number of plant fault occurred in the year 2008 (2171.27 hr) and the minimum occurred in the year 2009 (1499.39 hr). In addition, **Figure 1** shows that there are relatively small numbers of operational faults within the period considered.

From **Figure 4**, it can be seen that the total outages from 2005 to 2009 are inconsistent, ranging from 3053.81 to 4811.29 hr. This shows that the trends of outages hours are unpredictable from year to year. There are many factors responsible for increasing and decreasing trend in total outages hours. These factors may include: difficulty to perform the maintenance activities, delay in

**Figure 2.** Unit by unit running hours.

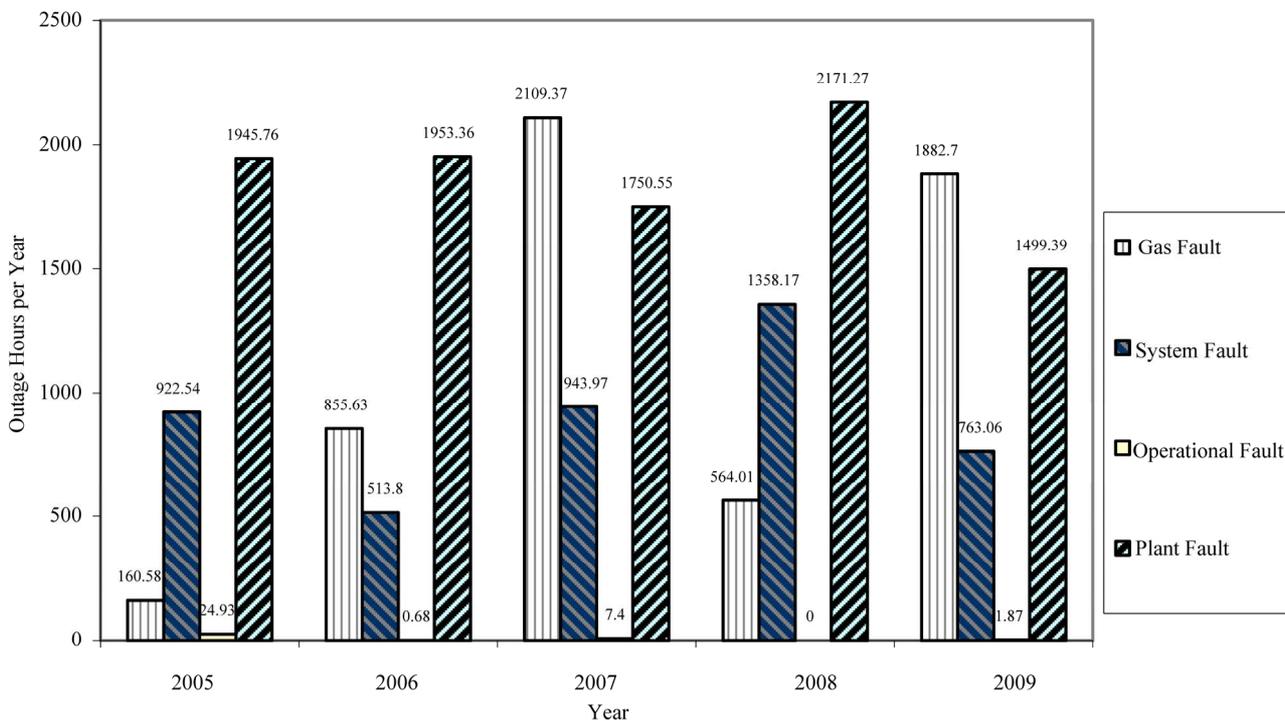

Figure 3. Outages hours per year according to fault classification.

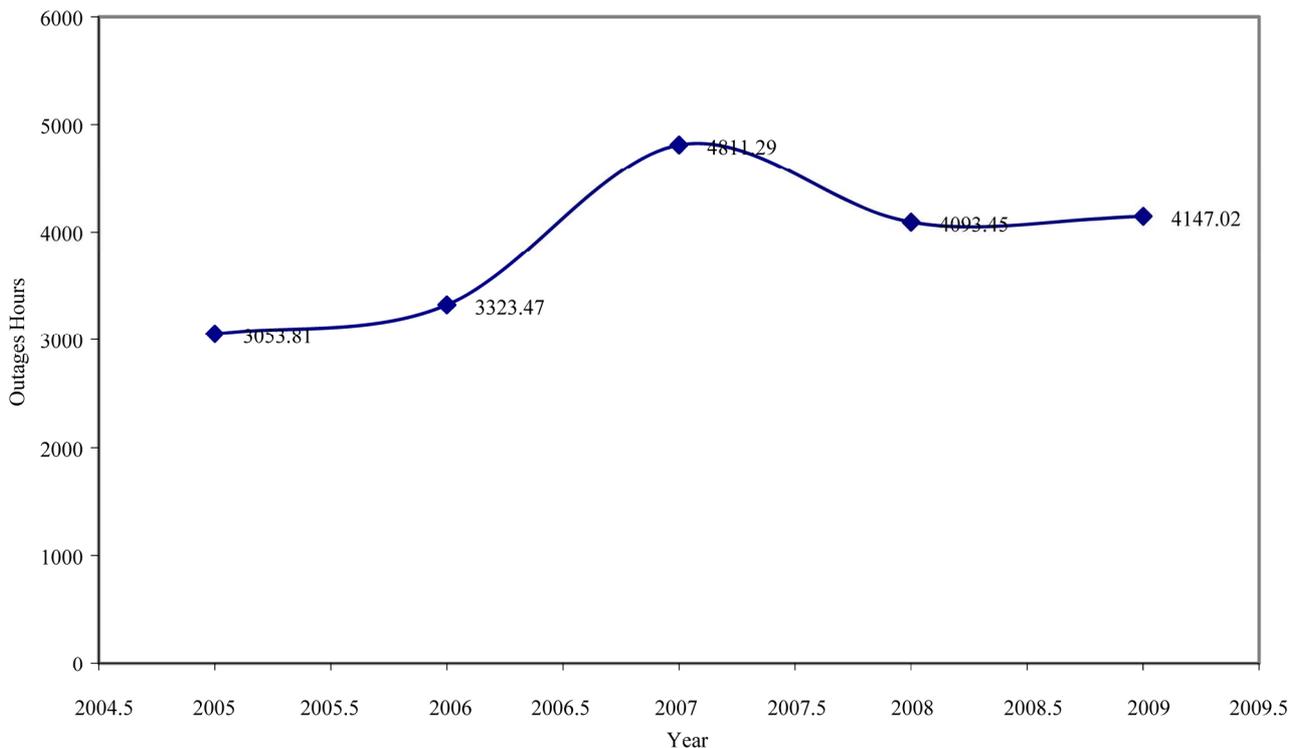

Figure 4. Total outages hours per year.

gas supply/gas limitation, shutdown due to failure of some critical components (e.g. steam leakages, system surge, system under-frequency, poor vacuum, super

heater leakage, boiler tube leakage etc.), delay in release of fund for replacement of parts and repairs and the skills of technicians or operators.

**Table 4. Number of failures per year at Egbin thermal power plant.**

Unit	Number of Failure

**6.1. Evaluation of Availability and Reliability of Egbin Power Plant**

The availability and reliability analysis was based on the available five units as at the time the data was collected. As stated earlier, unit 6 is presently not functional. The application of reliability and maintenance (R & M) principle in Egbin thermal power station plants/equipment requires that the system/component availability be defined in terms of Mean-Time-between-Failures, MTBF and Mean-Time-to-Repair, MTTR. MTBF is related to the duration of outages. By definition, availability (*A*), failure rate ( $\lambda$ ), MTBF and MTTR are computed as:

$$MTBF = \frac{1}{\lambda} = \frac{\text{Total operating time}}{\text{No of failures}} \tag{1}$$

$$MTTR = \tau = \frac{\text{Total outage time}}{\text{No of failures}} = \frac{1}{\mu} \tag{2}$$

When these two factors are known for any given system or component, then the availability (*A*) is expressed as:

$$A = \frac{MTBF}{MTBF + MTTR} = \frac{1}{1 + \lambda\tau} = \frac{\text{Uptime}}{\text{Uptime} - \text{Downtime}} \tag{3}$$

where

$$\lambda = \frac{\text{No of failurs between maintenance}}{\text{Total operating time between maintenance}} = \text{failure rate } i.e. \text{ number of failures/unit time}$$

$\tau$  = duration of outage

$\mu$  = repair rate =  $1/\tau$

$$\text{Reliability, } R(t) = \exp(-t/MTBF) = \exp(-\lambda t) \tag{4}$$

where *t* = period of failure

$$\text{Maintainability (} Mt) = \exp(-t/MTTR) = \exp(-\mu t) \tag{5}$$

Utilization (efficiency)

$$= \frac{\text{Actual work hours}}{\text{Max. potential hours of operation} + \text{delay hours}} \tag{6}$$

Figures 5 to 10 show the result of availability (*A*), MTTR and MTBF at Egbin power plant.

**6.2. Plant Availability**

This section deals with analysis of the entire plant availability for the year 2009.

Total outages hrs/yr = 4147.02

Number of failures/yr = 174

MTTR = 4147.02/174 = 23.38 hrs

MTBF = 4612.98/174 = 26.51 hrs

Availability (*A*) = 26.51/50.31 = 0.527

Unavailability = 1 - *A* = 1 - 0.527 = 0.473

Capacity factor = 1100/1320 = 0.833

The theoretical energy generation that could be obtained from available power (1100 MW) if the plant worked every second of the year non-stop is 1100 × 8760 = 9,636,000 MWh.

While the theoretical maximum energy that could be attained from the installed power (1320 MW) if the plant worked every second of the year non-stop is 1320 × 8760 = 11,563,200 MWh.

The actual total energy generated in 2009 is 3,383,869 MWh.

Generation Utilization index = Actual generation/ Available capacity = 35.11%.

Capacity Utilization index = Available capacity/Installed capacity = 29.26%.

**7. Discussion**

Analysis of the available data of Egbin thermal power plant for the years 2005 to 2009 has been carried out and the results for MBTF, MTTR and Availability (*A*) are shown in Figures 6 to 10. The results of this study show that the five units presently functional at the station are not in good condition. This is because, the availability of the units vary from 28.79 to 94.53 percent.

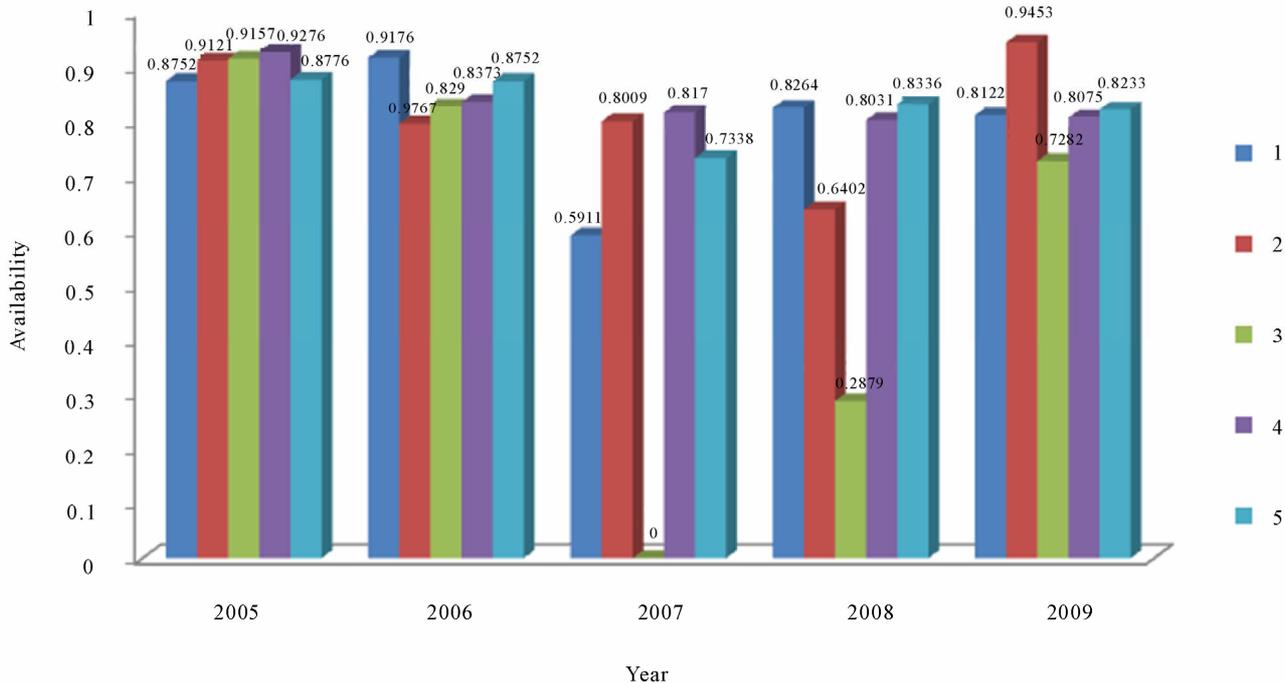

Figure 5. Variation of unit availability for each year.

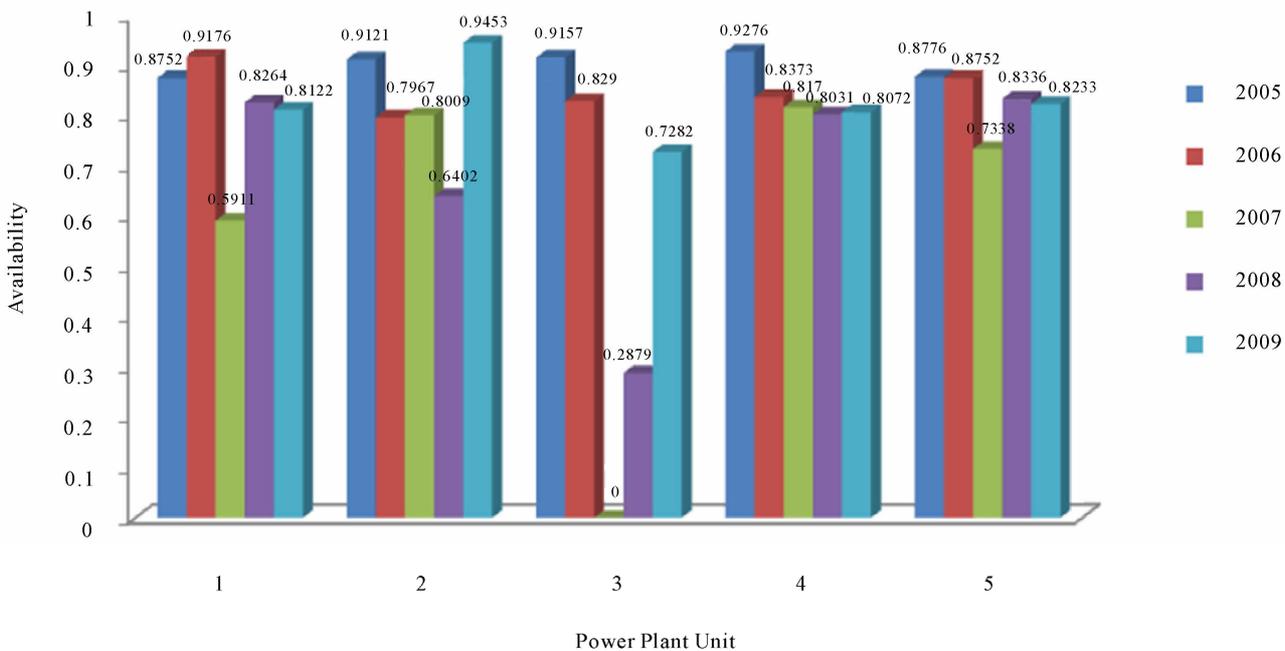

Figure 6. Unit availability per year.

The availability of the plant is very low compare to world class power industry. **Figure 5** shows that Unit 3 has the lowest availability (28.79%) in the year 2008 and unit 2 has the highest availability (94.53%) in 2009. **Figure 6** shows variation in availability of each unit within the period considered. The availability of unit 1 varies

from 0.5911(2007) to 0.9176 (2006), unit 2 varies from 0.6402 (2008) to 0.9453 (2009), unit 3 varies from 0.0 (2007) to 0.9157 (2005), unit 4 varies from 0.8031 (2008) to 0.9276 (2005) and unit 5 varies from 0.7338 (2007) to 0.8776 (2005). This analysis shows that unit 4 has highest availability within the period considered. The mean

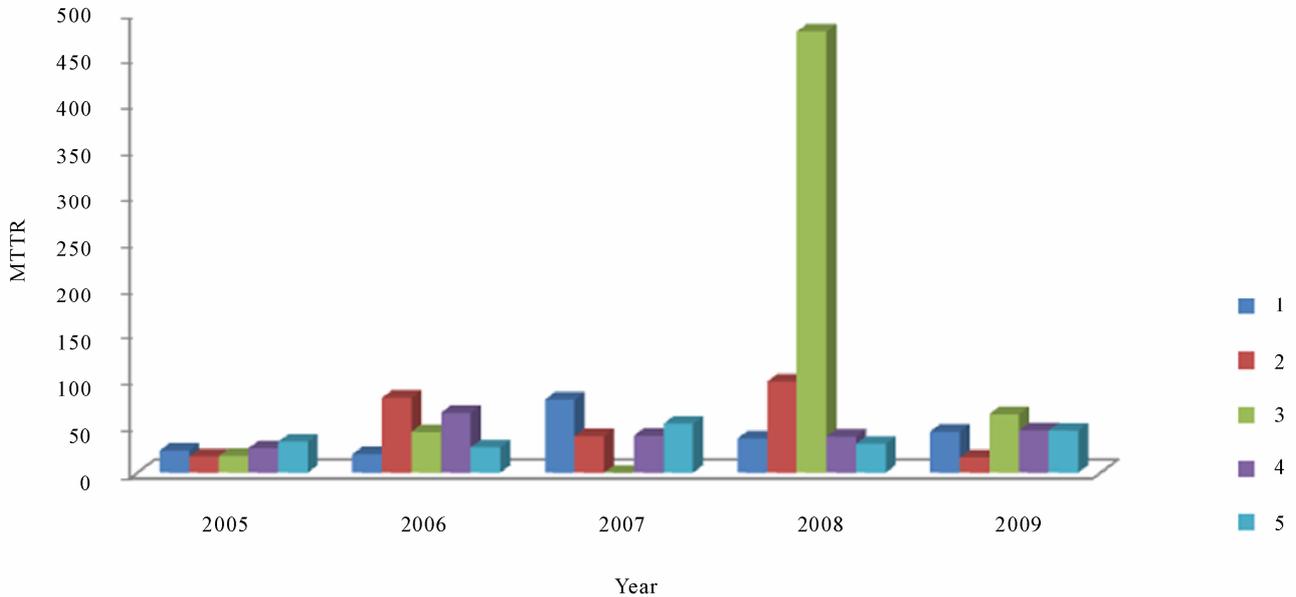

Figure 7. Variation of unit MTTR for each year.

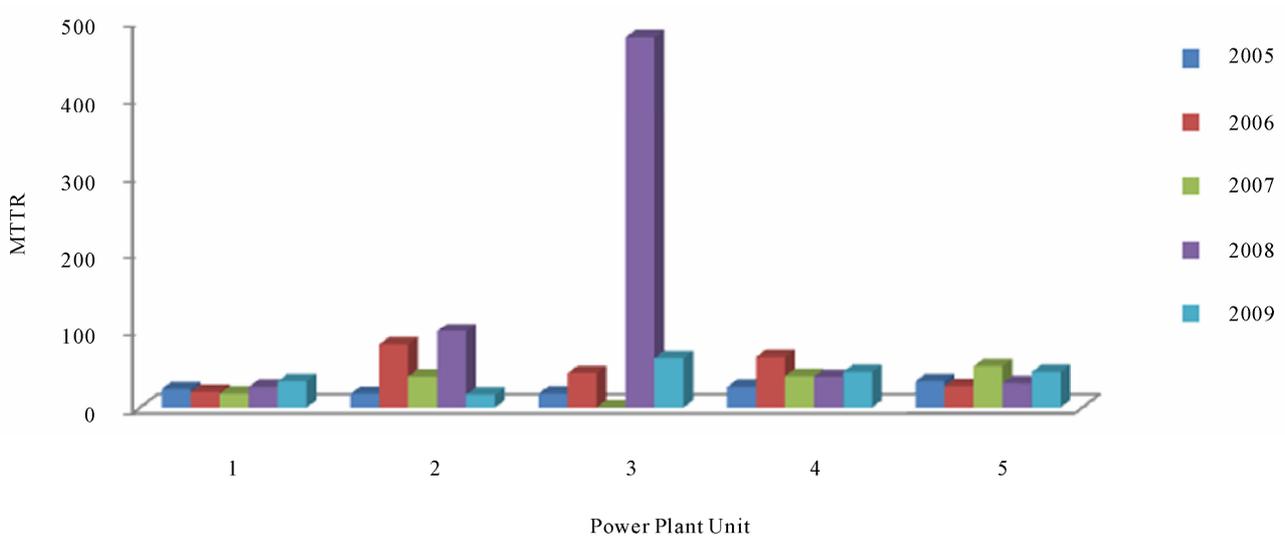

Figure 8. Unit MTTR per year.

time to repair (MTTR) ranges from 16.52 to 479.85 hours. **Figures 7 and 8** show that Unit 3 has the highest MTTR in 2008 and unit 2 has the lowest in 2009. This shows that lot of time was spent on unit 3 in 2008 in order to put it to operation. From this it can be concluded that there is inverse relationship between the component/equipment availability and failure rate. **Figures 9 and 10** show the unit mean time between failures (MTBF) from 2005 to 2009. Unit 4 has the highest MTBF of 338.58 hrs and 333.41 hrs in 2005 and 2006 respectively; unit 1 has the lowest MTBF of 115.07 hrs in 2007. This shows direct relation between MTBF and unit availability. As the unit with highest MTBF has highest availability.

In general, considering the whole plant availability with the available data for the year 2009, it was found that the plant availability was 52.7 percent with capacity factor of 0.833. The actual energy generation in 2009 was 3,383,869 MWh, while the estimated theoretical energy generation that could be obtained from available power (1100MW) if the plant worked every second of year non-stop is 9,636,000 MWh. From the available data on the plant, the major factors responsible for this wide different between the actual energy generation and theoretical energy generation in the year 2009 include plant fault which caused 1499.39 outages hours. This comes from shut down due to re-heater leakage, partial

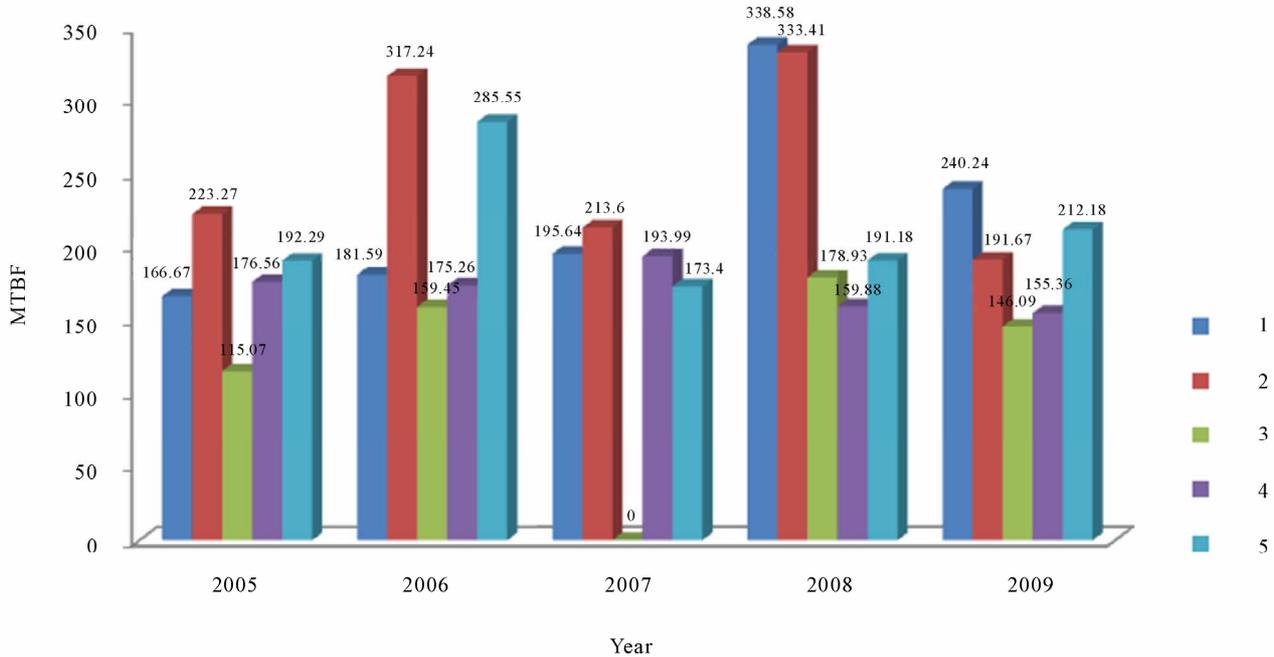

Figure 9. Variation of unit MTBF for each year.

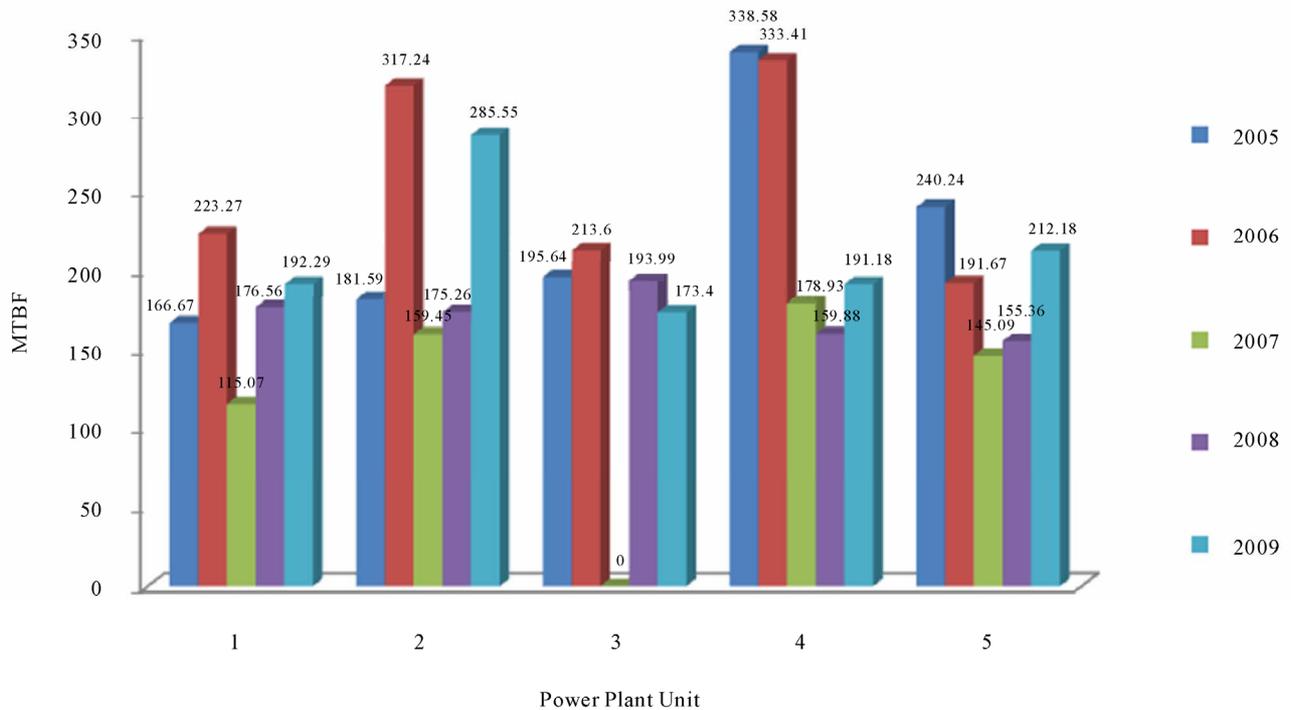

Figure 10. Unit MTBF per year.

loss of flame, vacuum decay, super-heater tube leakage etc. In addition to this, other fault is gas fault which caused 1882.7 outages hours. This is as a result of disruption or shortage of gas supply to the plant. Due to this fault, the affected unit has to be shut down until gas sup-

ply is restored. These two factors play major role in the availability of thermal power plant.

The trend of power availability reflects how effectively managed the station in terms of down time, spare parts, availability of funds, pipeline vandalization etc.

## 8. Conclusions

The reliability of power plant unit is one of the most important performance parameters which reflect the quality and standards. The great care and effort devoted to increasing the reliability and quality of electrical power is an indication of the economic implication for the power industry.

This study has investigated the reliability and availability of Egbin power station units in relation to implementation of preventive maintenance programme. The availability analysis shows different result for each unit indicating differences in their system installation, maintenance and operation. As the availability of each unit varies from 28.79% to 94.53% for the five years data base considered. Also, the availability of the entire plant for the year 2009 was computed as 52.7%, while the generation utilization index is 35.11% and capacity utilization index 29.26%.

The availability and reliability of the turbines presented in this study reflect on site behavior, including the effects of changes in auxiliary systems maintenance policy. Identifying the effects of component failure on the system under analysis, based on the failure effects classification, a maintenance policy can be formulated to reduce their occurrence probabilities.

Better aims and specific targets are needed for the Egbin power station to improve maintenance management systems and productivity. This should be based on a new maintenance paradigm that will improve maintenance control and PM activities. The managers must formulate wise strategies, make decisions and monitor progress against plans by collecting, retrieving and analyzing data.

To reduce downtime and achieve high production capabilities, the aim should be to find ways to increase equipment reliability and extend the equipment's life through cost effective maintenance. To achieve these, PHCN must move away from the traditional reactive maintenance mode to proactive maintenance and management philosophies. There should be maintenance processes that fully address Total Quality Maintenance (TQM) and Total Productive Maintenance (TPM) operating modes. Such change requires a complete shift to a Total Planned Quality Maintenance (TPQM) approach, which is a maintenance and management philosophy that advocates planning all maintenance (*i.e.* preventive, predictive and corrective), as well as the control of quality in maintenance operations.
