Abstract

This paper attempts to evaluate the banding patterns of non-gluten protein isolates from the grain of durum wheat varieties. Under reduced condition, polyacrylamide-gel electrophoresis has revealed a number of different sized albumin and globulin protein bands. The electrophoretic pattern of globulin showed more polymorphisms than that of albumin. High polymorphism, both in band intensity and occurrence, was observed between 15 kDa and 35 kDa. Most of the protein bands were scored in the range of 10 kDa and 85 kDa in the two protein fractions. At a cutoff point 2.5, cluster analysis based on the SDS-PAGE of globulin proteins classified the durum wheat varieties into three major family groups. Generally, the experiment showed the suitability and usefulness of globulin protein fractions as a genetic marker in discriminating durum wheat genotypes.

Keywords

Albumin, Durum Wheat, Globulin, Polymorphism, Seed Protein

1. Introduction

Seed proteins are one of the most abundant and highly diverse class of biomolecules. The gliadin and glutenin proteins are the most commonly used protein markers for the identification of germplasms in genetic diversity analysis. The reason for this is that the gluten proteins are highly diverse and they are found abundantly [1]. The use of electrophoretic patterns of albumin and globulins for genetic diversity analysis are less common and barely used. Albumin and globulin proteins, also known as Leukosin and Edestin, respectively, represent 10% to 30% of total flour protein [2] [3]. These proteins are found mainly in the embryo and seed aleurone layer [4]. Albumins are believed to have roles as nutrient reserve for the germinating embryo, defense to insects and fungal pathogens, and influence on grain hardness [5] [6]. In addition, they also act as enzymes and enzyme inhibitors [7].

Apart from their structural, protective and metabolic functions some high molecular weight albumins and certain globulin proteins are believed to have storage function too [8] [9].

From nutrition point of view, albumin and globulin proteins are considered to be best in terms of their amino acid compositions. These protein fractions have higher lysine and methionine contents as compared to the gliadin and glutenin proteins [10]. The most common albumins and globulin proteins are *a*-amylase/ trypsin, serpins and purothionins [5].

Evaluation of cultivars using protein markers has a potential to give more reasonable information. Many of the seed proteins constitute a multigene family that are transmitted from generation to generation. Therefore, they are used as useful indicators in varietal identification and as a breeding tool to select plants with desirable trait [4].

The main objective of this research was to study the composition and electrophoretic pattern of non-gluten protein fractions from durum wheat.

2. Materials and Methods

2.1. Experimental Materials

Twenty improved durum wheat varieties of Ethiopian origin were included in the present study. Their local names, pedigrees, origin and adaptation areas are given in **Table 1**. The seed samples grown in Ethiopia in 2017 were used in this experiment. All analyses were conducted in the same year in the Department of Crop Science and Biotechnology, Jeonbuk National University, Jeonju, South Korea [11].

2.2. Protein Fractionation

One hundred milligrams of finely ground wheat flour was used to sequentially extract the four major protein fractions by the Osborne procedure [12]. Albumin proteins were extracted by deionized water with intermittent vortexing every 10 min for half an hour. The supernatant obtained following centrifugation at 2000 rpm for 5 min (albumin extract) was saved for further analysis. The procedure has been repeated twice to remove all the albumin fractions before proceeding to the next step.

The pellet from the final albumin extraction was used to extract globulin fraction. The extraction was conducted using 0.5 N NaCl for 30 min with intermittent vortexing every 10 min. In similar fashion, the supernatant obtained following centrifugation at 2000 rpm for 5 min (globulin extract) was kept in

refrigerator for further analysis. Extraction was repeated twice to avoid carry over (cross-contamination) of globulin fraction to the subsequent steps. The centrifugate was washed with distilled water to reduce the effect of the salt in the extraction of other proteins in the subsequent steps.

2.3. SDS-PAGE Analysis

Protein fractions were analyzed under reduced conditions (in the presence of beta-mercaptoethanol) using discontinuous SDS-PAGE [14]. The electrophoresis was conducted in 12% separating gel and and 6% stalking gel. Separation of pro-

tein bands was conducted at a constant voltage of 200 V until bromophenol blue passes the stacking gel and then raised gradually to 500 V. Following electrophoresis, the gels were stained with 0.2% (w/v) CBB in 45% (w/v) methanol and 10% (w/v) acetic acid under constant agitation. Destaining was conducted in 45% methanol and 10% acetic acid solution.

The acrylamide solution was made from 30 g acrylamide monomer and 0.8 g bisacrylamide in distilled water. The resolving gel buffer was composed of 36.6 g Tris base and 40 mL of 0.1 M HCl and the pH was adjusted to 8.8. Stacking gel buffer composition was 6.06 g Tris base dissolved in 40 mL of distilled water. The pH of the stalking gel adjusted to 6.8 using weak acid.

Molecular weights of the protein bands (polypeptides) were estimated by using Thermo Scientific PageRuler Plus prestained Protein Ladder having a mixture of nine blue, orange, and green dyed proteins (10 - 250 kDa).

The protein bands on the destained gel were quantitated using AlphaEaseFC 4.0 software (Alpha Innotech Corporation, San Leandro, CA).

2.4. Determination of Protein Content

The extracted samples were mixed with a buffer containing 2 mM DTT, 0.1% Triton X-100 and 63 mM Tris-HCl (pH 6.8). The reagent solution was prepared by mixing the Bradford reagent (100 mg of CBB G-250 in 50 ml of 95% ethanol) with 100 ml of 85% ortho-phosphoric on a magnetic stirrer. The resulting solution was filtered through filter paper (Whatman) and stored in a dark bottle at 4°C. Standard curve was plotted by using seven concentrations [0 (blank), 0.2, 0.4, 0.6, 0.8, 1, 1.2 mg/ml] of bovine serum albumin (BSA) against a blank (deionized water). Absorbance was measured from 1 ml of the reaction solution at 595 nm after 3 min of incubation at room temperature. The absorbance of blank was subtracted from standards concentrations to obtain the actual concentration of the sample. Quantification of proteins was performed in triplicate. The spectrophotometric absorbance was read on Biotek Synergy 2 Micro-plate reader instrument using a Gen5 computer software program.

The absorbance reading was converted to protein concentration using a standard curve established with BSA dissolved in lysis buffer. The protein content was calculated using the following equation:

$$Protein(\%, w/w) = CVD/M \times 100$$

where *C* is protein concentration (mg/ml) obtained from standard curve.

V is volume (ml) of the lysis buffer used to resuspend the biomass.

D is the dilution factor.

M is the amount of biomass (mg).

2.5. Micro-Kjeldahl Method

The total protein content of the durum wheat varieties was estimated by micro-Kjeldahl method using nitrogen analyzer by taking 5.7 as a conversion factor. Three replicate measurements were taken to estimate error variance.

2.6. SDS-Sedimentation Test

SDS-sedimentation volume was measured following Axford method [15].

2.7. Statistical Analysis

All analyses were replicated three times and means were compared by Fisher's least significant differences (LSD) at P < 0.05 and P < 0.01 using SAS statistical package [16]. Dendrogram was constructed from the electrophoretic data using Xlstat software.

3. Results and Discussion

3.1. Distribution of Protein Fractions

The water soluble albumin and dilute salt soluble globulin proteins were separated and quantified. It is found that variety *Robe* had the highest albumin content (19.35%) while *Boohai* (15.34%) lowest. Albumin concentrations in wheat grain ranging from 18% to 21% have been reported elsewhere [17].

In globulins, the highest amount was recorded for varieties *Cocorit*-71 (10.70%), while for *Gerardo* (6.07%) the lowest. The albumin and globulin content of most common wheat proteins is reported to be in the range of 20% - 25% [2]. Our findings also confirmed similar results with an average albumin and globulin content of 27%.

The data presented in **Table 2** showed that, the content of total protein is statistically significant (P < 0.01) suggesting the presence of considerable variation in protein content among durum wheat varieties. In the present study, protein content in grain of durum wheat ranged from 8.08% (*Candate-Utuba*) to 14.28% (*Boohai* and *Tob*-66). Other previous research findings reported grain protein content in the range of 7 to 12.5 among 15 Ethiopian durum wheat varieties [18]. The protein content of grain is affected mainly by genetic factor. However, environment and many other factors may also play a great role in determining the protein content of the crop [19] [20].

The experimental results based on the absorbance reading revealed gliadin proteins (also known as large monomeric gluten proteins), to be predominant protein fractions (51.47%). Albumins and globulins accounted only for 27% of the total protein. The ratio of gliadin to glutenin proteins was close to 4:1.

The correlation between total protein content and individual protein fractions was evaluated statistically (results not shown here). There was no significant correlation among the individual protein fractions and the total protein content. Contrary to the present finding, there are reports of strong relationship between albumin-globulin fractions and total protein content [21]. Sedimentation volume test had some positive correlation with protein content and this shows that the volume of sediment is a good indicator of protein content.

3.2. SDS-PAGE Pattern

The albumin-globulin proteins were separated and identified by electrophoresis.

Varieties	Total Protein - (mg/100mg flour)	Soluble (non-gluten,)		Large	Soluble and	Ratio of	SDS

w/w, the proportion of individual protein fractions from total protein expressed in weight to weight basis.

The electrophorograms show the patterns and molecular weight distribution of albumin and globulin proteins (**Figures 1-3**).

Around 10 to 16 different polypeptides were detected in the globulin fraction. Their molecular weight ranged from 10 to 70 kDa. Among the seven prominentglobulin polypeptides identified, five major ones' molecular weight were 15, 20, 35, 55, and 70 kDa, respectively (**Figure 1**). These results are consistent with previous research findings [3] [22] which reported globulin polypeptides ranging from 12.4 to 76.4 kDa.

In the globulin proteins, high polymorphism in both band intensity and occurrence was observed in those with molecular weights between 15 and 35 kDa. The presence of polymorphism in this molecular weight range suggests that

globulins could also be used as suitable and useful genetic markers to discriminate genotypes.

A major cause of polymorphismin any specific protein is known to be related with gene silencing [23].

The gel electrophoresis result of albumin proteins did not show any significant variation among the genotypes. Almost all bands were monomorphic across all wheat genotypes. Molecular weight of the polypeptides ranged from 10 to 65 kDa and the number and position of bands were similar for all varieties (**Figure 2**). Generally, around 20 different polypeptides were detected in the albumin fraction. Likewise, the number of bands in globulin proteins was from 10 to 16. This is in agreement with other previous research findings [3].

The heterogeneity of albumin and globulin was also revealed by the banding patterns of the mixture of globulin and albumin fractions (**Figure 3**). The varietal heterogeneity of these fractions was more similar to that detected by globulin fractions. Diversity of albumin and globulin proteins in wheat varieties was demonstrated in the earlier research works [24]. This pioneering research on albumins has reported the presence of three protein components in the water soluble proteins. Following this finding, there were some contradicting reports on the presence of noted molecular weight heterogeneity in both in the water-soluble and salt-soluble proteins.

3.3. Genetic Relationship among Varieties

The dendrogram constructed based on the electrophoretic data of globulin protein fractions of the 20 durum wheat varieties is shown in **Figure 4**. There was fairly clear separation of the varieties. The cluster analysis result of globulin proteins classified the durum wheat varieties into three major lineage groups at a cutoff value 2.5. The varieties in cluster 3 were composed of widely adapted types, whereas the varieties in cluster 1 and cluster 2 were primarily from highland areas.

4. Conclusion

The present finding has revealed fairly significant polymorphism in the globulin protein fractions. Variability was observed in the bands corresponding to molecular weights from 15 to 35 kDa. Contrary to this, albumin proteins did not show any significant variation among genotypes. Generally, apart from the gliadins and glutenins, the globulin has also a potential to serve as biochemical markers for evaluation of polymorphism and genetic diversity in durum wheat varieties. Use of globulin polymorphism in diversity studies could facilitate efforts to improve the quantity and quality of durum wheat varieties and could influence the selection of better raw materials for improved agronomic traits.
