Abstract

Disease management is often complicated by the presence of multiple types of pathogens; in an organic system, it is appropriate to develop disease control strategies. The available literature so far reflects that the management of important disease of tomato is through the integrated approaches and very few organic approaches have been tried with various degree of success. Bio-priming of seeds with biocontrol agents (*Trichoderma viridae*, *Trichoderma harzianum* and *Pseudomonas fluorescens*) in combination with different biofertilizers (*Azotobacter*, *Azospirillum* and PSB) and organic manures (FYM and vermi-compost) were tested against disease incidence and health management of tomato seedling under nursery as well as field conditions. The studies were conducted during two successive years (2012-2013) at farmer's field with the objective to combat with the increasing disease incidence of three major disease damping-off, fusarium wilt and buckeye rot from nursery stage to the final harvesting. The study focused on the use of biocontrol agents as the suitable alternative to chemical pesticides with sustainable disease management without pesticide residues in foodstuff. The bio priming of seeds with fungal antagonist *Trichoderma viridae* and *harzianum* and bacterial antagonist *Pseudomonas fluorescens* significantly improved the germination behavior of tomato seeds as compared to untreated control. Highest mean germination (93.1%) and seedling vigour (953.33) was recorded in Treatment 3 (FYM @ 200 q/ha + *Azospirillum* + PSB + *Trichoderma harzianum* (4 kg/ha each) and lowest in control (60.3%) and (304.83), thus indicating a significant per cent increase in seedling emergence (54.4%) and seedling vigour (95.23%). A considerable reduction in disease incidence (pre and post) of damp-

*Corresponding author.

ing off was observed in treatment T₃ and T₄ (VC @ 50 q/ha + Azospirillum + PSB + *Trichoderma herzianum* @ (4 kg/ha) with 45.6% and 35.4% respectively). Treatment T₃ proved highest in terms of yield (665 Kg/Ha), Hence these diseases can be managed by successful application of Biocontrol agents.

Biocontrol Agents, Biofertilizers, Disease Incidence, Organic Manure, Tomato, Yield

1. Introduction

Solan lalima is an open pollinated and indeterminate variety of tomato having superiority over the present tomato hybrids available in the markets in terms of fruit quality and productivity. Being open pollinated variety, it's a suitable option for organic cultivation. The farmer can produce its seeds at their own farm. The importance of healthy seed selection and disease free nursery raising is the most important requirement to have the desired crop performance, lower the abiotic and biotic yield limiting constrains, reduce the incidence of insect-pest-disease (IPD) and to fetch remunerative economic return to the farmers. The reduction in potential yield in hills by the farmer is due to the increasing susceptibility of pre and post emergence of insect-pest and diseases at regular intervals, right from the nursery raising to the final harvesting period, where the incidence of most pathogenic diseases like Damping off (*Pythium aphanidermatum*), bacterial wilt (*Ralstonia solani*) and fusarial wilt (*Fusarium oxysporum*) etc. can be witnessed which ruin the crop diversity and quality to the most worst level. The problem becomes more severe when the crop is attacked by the cascade of diseases one after the other. The use of conventional chemical pesticides is considered most preferred practices to manage the outbreaks of these diseases, but the indiscriminate chemical approach to deal with these hazards has contributed to adverse effects like soil acidity, impairing soil physical conditions, reducing beneficial microbial population and continuously degrading organic matter, increasing plant susceptibility to insect-pest-diseases and decreasing soil lives.

The use of biocontrol agents (BCA's) in combination with organic manures and biofertilizers is the suitable alternative to chemical applications with sustainable disease management without pesticides residues in food stuffs, development of resistance in plant pathogens and appearance of new strains of these pathogens. The biocontrol agents are highly effective, inexpensive with excellent shelf life and suitable method of delivery [1]. Tomato is playing an indispensable role in the economic upliftment of hilly area farmers in form of off season crop in the mid hills of Himachal Pradesh. Tomato produced in Himachal Pradesh during June to November becomes off season vegetable in the markets of North Indian plains fetching very remunerative prices to farmers. The area and production of tomato crop in India, H.P. and Solan district is summarized in **Table 1**.

Determining the burning criteria of food quality and safety concerning each individual, an organic strategy can prove a miracle in increasing crop productivity, managing insect-pest and diseases, lowering pesticide residues an ultimately boosting up the best economic returns to the farmers.

Keeping in view the above raised priorities, the present studies were undertaken to test:

1) The efficacy of different combinations of organic manures, biofertilizers and BCA's for the management of various diseases, so as to integrate it in disease management schedule at farmer's field.

2) To access the effect of the organic treatments on the productivity and incidence of important diseases.

Table 1. The area (Ha) and production (MT) of tomato crop in India, H.P. and Solan district (2011-2012).

S.NO.	Production (MT) and area (Ha)		
	Country/state/district	Area (Ha)	Production (MT)
1	India	479,200	8,585,800
2	Himachal Pradesh	9555	3.4
3	Solan	4298	195,900

2. Materials and Methods

2.1. Manures and Bio-Fertilizers

FYM (Farm yard manure), VC (Vermicompost), AZO (Azotobacter), PSB (phosphate solubilizing bacteria), Neem cakes, AZS (Azospirillum), *Trichoderma viridae*, *Trichoderma harzianum*, *Pseudomonas fluorescens* and Asafetida were procured from Poabs Green Biotech Pvt Ltd Palghat (Kerala).

2.2. Experimental Design and Location

A field experiment was conducted at farmer's field in basal village of Solan block of HP, during the year 2012-2013. For the studies commercially grown vegetable tomato (solan lalima, organically certified) was selected. The trial was laid using a RBD (Randomized Block design) with three replications. A whole of 7 treatments and 3 replications were worked out. Under organic treatments, no chemical fertilizers and pesticides were used, rather than a combinatorial approach combining the use of organic manures, biofertilizers with addition of biocontrol agents were used. The treatments ranged from T₁ to T₇. The detailed descriptions of these treatments are given in Table 2.

All the treatments were comparatively analyzed with respect to production and profitability in terms of technology used for seed treatment, nursery raising, manurial and fertilizers schedule, sowing times and spacing etc.

2.3. Seed Treatment

The treatments comprised of seed treatment which included treating seeds with fungal strain *Trichoderma viride* (Poabs Biotech Pvt. Limited) @ 4 g/kg of seeds. The bed size for raising nursery was 1/3 m x 15 cm flourished with well rotten FYM and VC @ 20 - 25 kg with combination of *Pseudomonas fluroscens* and *Trichoderma herzianum* @ 1.0% as biocontrol agent and PSB as biofertilizers @ 1.5 kg, during the first week of March during both the years.

2.4. Soil Treatment

Soil treatment was done by applying a combination of *Trichoderma viride* with panchagavya/jeeva amrit @ 4 g/L.

2.5. Seedling Treatment

The 15 - 20 days old seedling was treated with 7 g/L neem soap spray.

2.6. Nursery Drenching

Nursery drenching was done with *Pseudomonas fluroscens* (10 g/L).

Lastly before transplanting seedlings to the main field they were dipped in suspension solution of asfoetida @ 100 g/5 L of water for 15 - 20 minutes. The protocol (ICCOA standard protocol) followed in field after trans-

Table 2. The organic treatments with detailed description.

Treatments	Treatments designed with detailed description
	Detailed description
T ₁	FYM @ 200 q/ha + <i>Trichoderma viride</i> @ 4 kg/ha
T ₂	VC @ 50 q/ha + <i>Trichoderma viride</i> @ 4 kg/ha
T ₃	FYM @ 200 q/ha + Azospirillum + PSB + <i>Trichoderma herzianum</i> (4 kg/ha each)
T ₄	VC @ 50 q/ha + Azospirillum + PSB + <i>Trichoderma herzianum</i> @ (4 kg/ha)
T ₅	FYM @ 200 q/ha + Azotobacter + PSB (4 kg/ha)
T ₆	VC @ 50 q/ha + Azotobacter + PSB (4 kg/ha)
T ₇ (control)	FYM @ 250 q/ha + chemical fertilizers (CAN @ 650 kg/ha, urea@) 650 kg/ha + pesticides (40 - 50 no. of sprays)

planting seedlings to main field is described in **Table 3**.

2.7. Observations

Observation were recorded on seedling emergence, vigour, incidence of disease (pre and post emergence), yield (Kg/ha) in comparison to an untreated control with reference to following under given parameters [2].

- Seedling emergence (%) = No. of seedlings emerging out of total germinated.
- Seedling vigour = (germination % x seedling length (cm) and % increase in vigour.
- Incidence of pre emergence rot (%) was calculated by;
Total number of seeds sown-germinated seeds
- Post emergence rot (%) was calculated by;
% of toppled plant out of germinated ones
- Incidence of diseases and reduction in disease: (%) (Damping off, buckeye rot and fusarial wilt).
Yield (Kg/ha) was recorded in comparison with the control.

2.8. Statistical Analysis

The data pertaining to estimation of various parameters was analyzed by Significance tests reported by analysis of variance (ANOVA) at $p = 0.05$ significance level with SPSS STAT 20 Software for (RBD) Randomized Block Design.

Table 3. Protocol followed during cropping period for 2012-2013 (ICCOA-International Competence Center for Organic Agriculture).

Protocol followed during Cropping period	
Activity	Technological Intervention
Plot size	1100 sqm
Preparation of land	Four ploughing followed by flanking and final lying out of experimental bed plots.
Variety selection	Solan lalima (Open pollinated)
Seed source	Procured from Department of Vegetable crops Dr. Y.S. Parmar-UHF Solan
Seed rate	400 g/ha
Seed treatment	<i>Trichoderma viridae</i> @ 4 g/kg of seed
Seed spacing	5 cm × 2 cm × 0.5 cm
Nursery raising	Beds of 1 m × 3 m × 20 cm to which FYM @ 20 - 25 Kg/or VC 5 - 6 Kg, <i>Trichoderma harzianum</i> @ 4 g/Kg and 1.2 Kg neem cakes were incorporated.
Seedling treatment	Neem soap spray (7 g/l) to 15 days old seedlings-Drenching of seedling with <i>Pseudomonas fluorescens</i> (10 g/L) before transplanting. Root Dipping of seedlings in solution of asafetida (100 g/5L water) for 25 - 30 minutes before transplanting to the experimental plots.
Soil fertility management	Application of organic manures and bio-fertilizers. Mixing of FYM @ 200 quintal/ha + VC @ 50 quintal/ha + neem cake @ 250 kg/ha at the time of forming ridges.
Irrigation requirements	Two watering, morning and evening for one week. One time watering for second week. Alternate day watering during third week of transplanting and 5 - 7 days interval irrigation during the cropping period depending upon the weather.
Weed management	Hand weeding was used. During the entire cropping period three hand weeding was done.
Staking	Bamboo poles having 8 feet height supported by CGI wires and plastic ropes were used as support system.
Crop protection	Insect pest and disease management was undertaken by using all the organic approaches that is installation of yellow sticky traps, spray of biopesticides NPV (Nuclear Polyhedrosis virus), placement of trio card, use of neem cake/neem extract, vermin wash, use of barrier crops and other bio control agents(<i>Trichoderma harzianum</i> -10 g/l of water), <i>Pseudomonas fluorescens</i> (10 g/l of water).

3. Results

The results obtained are presented and discussed under the following headings:

3.1. Nursery Trials

The nursery stage was set up with six designed organic treatments against an untreated control (farmers practice T₇) (**Figure 1**). Treatments T₃ (FYM @ 200 q/ha + Azospirillum + PSB + *Trichoderma herzianum* (4 kg/ha each)) was found to be most effective in all aspects of studies as stated under succeeding headings:

Seedling Emergence and Vigour Index

Biopriming of tomato seeds with *Trichoderma* isolates (*T. viridae* and *T. herzianum*) and bacterial antagonist (*P. fluorescens*) in combination with devised organic treatments improved the seed germination % and seedling vigour index to a significant level ($p = 0.05$). Highest mean germination (93.1%) was recorded in treatment T₃ (**Table 4(a)**) with a vigour index of 953.33, followed by T₂ (89.4% and 767.7%) and T₄ (85.8% and 813.6%) respectively, resulting in an maximum increase of 54.4% in seed emergence and 95.23 in seedling vigour index over untreated control. Thus there was significant increase (**Figure 2**) at ($p = 0.05$) in root length ($p = 0.01$), shoot length ($p = 0.01$), no. of roots and internodal length ($p = 0.001$) being highest in treatment T₃ (**Table 4(b)**) as compared to an untreated check (T₇) which ultimately enhanced the seedling vigour index ($p = 0.01$) (**Figure 3**).

All the bioformulations proved significantly effective in reducing the pre and post-emergence damping-off disease in tomato nursery compared to an untreated check. Maximum mean reduction (45.6%) in pre emergence rots while 58% reduction in post emergence rots with treatment T₃ was recorded. T₄ and T₂ were at par with 35.4% reduction in pre emergence disease incidence and 59% and 39.3% post emergence disease reduction as compared to untreated control. From the data presented in **Table 5**, it is inferred that bioagents were found to be more effective in checking the post emergence rots where the disease incidence was reduced to a broader level (59%) as compared to pre emergence rot reduction level (45.6%). All the parameters were significantly increased ($p = 0.01$) at $p = 0.05$.

RDI-reduction in disease incidence.

3.2. Field Trials

The healthy nursery when transferred to field (**Figure 4**) resulted in considerable reduction in disease incidence and thus healthy tomato fruits were obtained with organically designed treatments as compared to farmers practice (control) as listed under following sub headings.

Survival Percentage of Seedlings in Field

The inferences drawn from **Table 6** revealed about the total successful emergence of tomato seedlings and percent reduction in disease incidence of fusarial wilt and buckeye rot (**Figure 5**) after transplanting to a main field. The results indicated that mean germination (81%) was reported in T₃, followed by 73.1% in T₅, respectively compared to control (59.5%).

However, the mean reduction in fusarial wilt and buckeye rot was found to be 47.4% and 38% under treatment T₃, indicating a considerable significant ($p = 0.01$) reduction in fusarial wilt and buckeye rot. The mean highest yield (**Figure 6**) was recorded in treatment T₄ (665 Kg/ha) over an untreated check (**Figure 7**) (649.5 Kg/ha) (**Table 7**).

4. Discussion

All botanicals were found significantly effective in increasing the seedling emergence and vigour index of tomato seeds under both nursery and field conditions. Similar findings on testing biocontrol agent's effectiveness against disease control, improvement in seedling vigour, seedling emergence were worked out in cauliflower [3] in capsicum, in tomato [4]. The results were at par with the work, where the use of *Trichoderma* isolates and bacterial antagonists used for biopriming of tomato seeds resulted in improvement in seed emergence (%), vigour (%) and biomass. The significant increase in the parameters (root length, shoot length, no. of roots and internodal length) resulted from the inherent capacity of bioagents which have been observed to protect the seeds from diseases as well as providing nutrients to germinating seeds by decomposition of organic matter. Secretion of hormones and release of nutrients from soil organic matter have been proposed as a mechanism involved in plant growth promotion [5] [6]. It is inferred that bioagents seem to be more effective in checking the post emergence rots where disease incidence is reduced to a broader level (59%) as compared to pre emergence rot reduction level (45.6%). The results of the studies are in consence with the findings of [7] where a similar inference was drawn with maximum disease reduction in post emergence rot incidence compared to pre rot incidence, due to the time required for multiplication of inoculum of bioagents in rhizosphere and collar region of seedling. Similar control of damping off has been observed through application of *Trichoderma viridae* and

SD: standard deviation; Level of significance (at $\alpha = 0.05$ by Fisher (F) test; Sig.-significance: HS^{***} = highly significant, best treatments bold and highlighted and control values highlighted but not bold, *data pooled for two consecutive years (2012-2013).

Pseudomonas fluorescence [8] [9]. The study resulted in successive control of damping-off as likewise observed by Kabdal *et al.*, (2010) in his findings and study for health management of capsicum nursery with the use of biocontrol agents. The total successful emergence of tomato seedlings and percent reduction in disease incidence of fusarial wilt and buckeye rot after transplanting to a main field indicated that maximum mean germination was reported in T₃, compared to control (64.3%) and the mean reduction in fusarial wilt and buckeye rot was found to be 63.2% and 42.3%. The present results are at par with the similar findings [10] where the application of antagonist fungus, Trichoderma as seed and soil treatment agent had significant effect in reducing disease incidence and increasing percent increase in yield over control, according to which simultaneous application of Trichoderma as seed priming and soil incorporation results in protective cover in the seed coat by rapid multiplication and boosting a greater strength to out compete the pathogens.

5. Conclusion

In the present investigation the combinatorial approach of integrating biocontrol agents in organic treatments

gave promising results for increasing the tomato germination (%) and seedling vigour under both nursery and field conditions, thus reducing the level of three major diseases-damping-off, fusarial wilt and buckeye rot and other harmful pathogens. The addition of microbial biocontrol agents during biopriming allows for colonization of the seed prior to planting and adds a new dimension to seed priming treatments, thus replacing the harmful synthetic fungicides which ruin the whole crop. The implication of the study is to control seed and soil borne pathogens with an application of biocontrol agents coupled with organic manures and biofertilizers right at prime nursery stage so that the incidence of diseases is reduced to a significant level so that it greatly lowers when the tomato seedlings are transplanted in main field, which in turn will help in maximum seedling survival and reduction in disease incidence.
