## ABSTRACT

Extruded dry dog food products claimed to have a probiotic ingredient of *Enterococcus faecium* (NCIMB10415) in the commercial available formulations under the brand name of ProBiotic LIVE (Bacterfield S.A., Luxembourg) were studied in the present work using a multichannel thermal activity monitor TAM III. Maximum specific growth rate, heat produced during different growth phases, and lag-phase duration were determined. The length of the lag-phase that can be used to determine the time necessary for the probiotic ingredient to restore its activity after consumption of probiotic containing extruded products was also measured. The calorimetric data confirmed the ability of the *Enterococcus faecium* to grow at the acidic pH conditions, modeling conditions of gastro-intestinal tract of dogs, and preserve its metabolic activity (viability) at the same level as at the neutral pH. The results obtained indicated that microcalorimetry was a precise and convenient tool for monitoring probiotic activity in complicated solid-state matrices.

**Keywords:** *Enterococcus faecium*; Probiotic Dog Food; Microcalorimetry

## 1. Introduction

Various attempts have been made to produce extruded feed or food product(s) with stable and viable probiotic bacteria count over the entire shelf-life period of the carrier product [1-3]. However, determination of the number of bacteria, and especially evaluation of their growth and metabolic activity in extruded food and feed products by means of *outplating* etc. cannot be considered sufficiently precise and convenient.

It has been shown that generation of heat by microbial cultures can be used for on-line monitoring of growth and metabolism of cells [4-10]. Very sensitive measurements of heat flows using microcalorimetry is one of the most attractive techniques for studying and monitoring of the metabolic activity of bacteria in opaque liquid media, and solid matrices [11-13]. It could be successfully applied in the studies of spoilage processes and shelf-life determination of products containing microbes [8,14-16], in fact in all cases where the possibilities of optical and other physical methods are limited due to the non-transparency of media [17,18].

Growth of bacteria in extruded dry dog food products under the brand name of ProBiotic LIVE (Bacterfield S.A., Luxembourg) claimed to contain a probiotic ingredient of *Enterococcus faecium* (NCIMB10415) were studied in the present work using a multichannel thermal activity monitor TAM III.

## 2. Materials and Methods

### 2.1. Samples

The experiments were performed with dry dog food in the form of extruded kibbles under a brand name of ProBiotic LIVE (Bacterfield S.A., Luxembourg) containing according to the producer viable probiotic bacteria *Enterococcus faecium* (NCIMB10415) during the entire period of product shelf-life (15 months) at room temperature. The concentration of bacteria as declared on the packaging is  $10^6$  cfu per gram of dog food in average. Three commercially available dog food products differentiated by dog age (adult and senior) and by taste (salmon and chicken formulations) were used in the experiments: ProBiotic LIVE Adult Chicken & Rice (AC), ProBiotic LIVE Adult Salmon & Rice (AS) and ProBiotic LIVE Senior Chicken & Rice (SC). All dog food samples used in the experiments were initially received in hermetically closed separate 1.5 kg bags, with expiry date/lot. nr. 23.11.2012 and used freshly in the middle of the claimed product shelf-life. All the bags were aseptically opened immediately before the experiments. Additionally, dry bacterial concentrate of the same strain of the bacteria as in the dog food (*Enterococcus faecium* NCIMB10415) provided by Probiotics International Ltd. (UK, Batch No BN 29094, expiry date 11.2013) was studied as a reference sample to dog food formulations.

The bacterial concentrate contained  $10^{10}$  cfu per gram of the powder according to the producer.

## 2.2. Sample Preparation and Experimental Conditions

Dry dog food kibbles of different types were ground and sifted to fine particles (less than 0.05 mm). Afterwards samples were weighed in sterile plastic Falcon tubes. The mass of each sample was approximately ~0.5 g. Samples were aseptically transferred into 3 mL autoclaved microcalorimetric ampoules. Depending on experimental conditions sterile MilliQ water, adjusted to pH = 2 (dog stomach equivalent pH [19]), or to pH = 7 (neutral value), was added to the ground dry dog food in mass ratio 1:1. pH was measured with pH meter S20 Seven Easy Mettler Toledo with calibrated InLab 413 Mettler Toledo electrode. All the solutions were previously sterilized by autoclaving at 121°C for 15 min. As a reference, samples of dry non-diluted bacterial concentrate were also analyzed.

In order to determine the initial bacterial concentration in dog food kibbles *outplating* on PCA (Plate Count Agar, Scharlau, Spain) was carried out for all three dog food formulations and dry bacterial concentrate.

## 2.3. Microcalorimetry

A TAM III (24-channels, TA Instruments, US), a heat conduction multi-channel microcalorimeter was used to monitor the growth of cells in dog food and bacteria concentrate samples. The construction and functioning of the TAM III calorimeter were described earlier by

Wadsö [8]. Microcalorimetric power-time curves were analyzed as described by Kabanova [10]. The calorimetric trials were performed at fixed temperature of incubation at 37°C (equivalent of dogs body temperature [20]) using 3 mL calorimetric ampoules. All the calorimetric experiments were carried out in three parallels and power-time curves obtained were normalized per gram of dog food. Averaged power-time curves of three parallel runs were used for the further analysis.

## 3. Results and Discussion

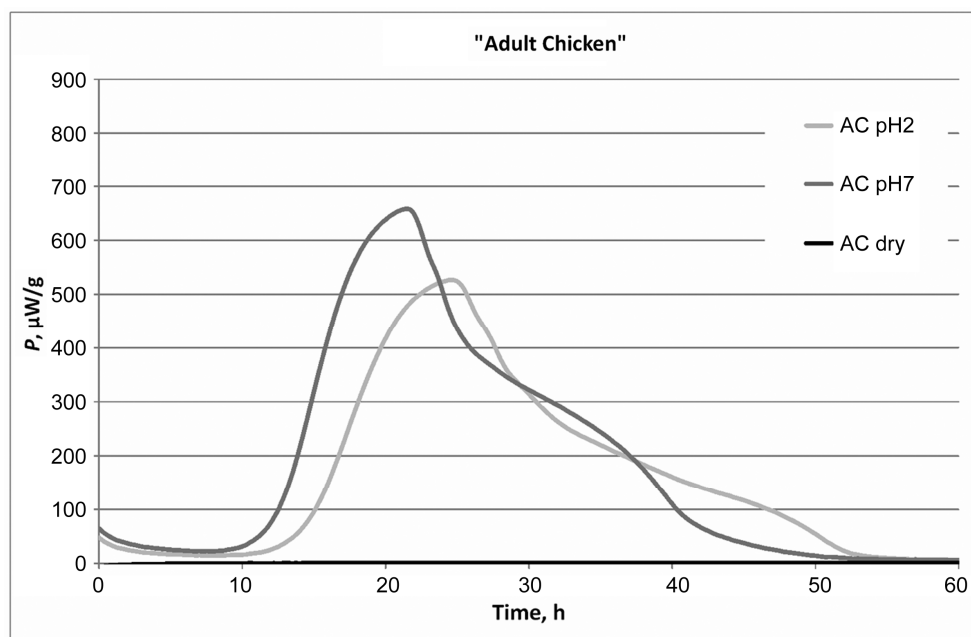

The averaged power-time curves of growth of *Enterococcus faecium* (NCIMB10415) in different formulations of dog food in case of dry samples and in moisturized samples at two different pH values are presented in **Figure 1**.

The standard deviation of the averaged power-time curves was 0.55  $\mu$ W, which was quite low, confirming high reproducibility of the calorimetric method.

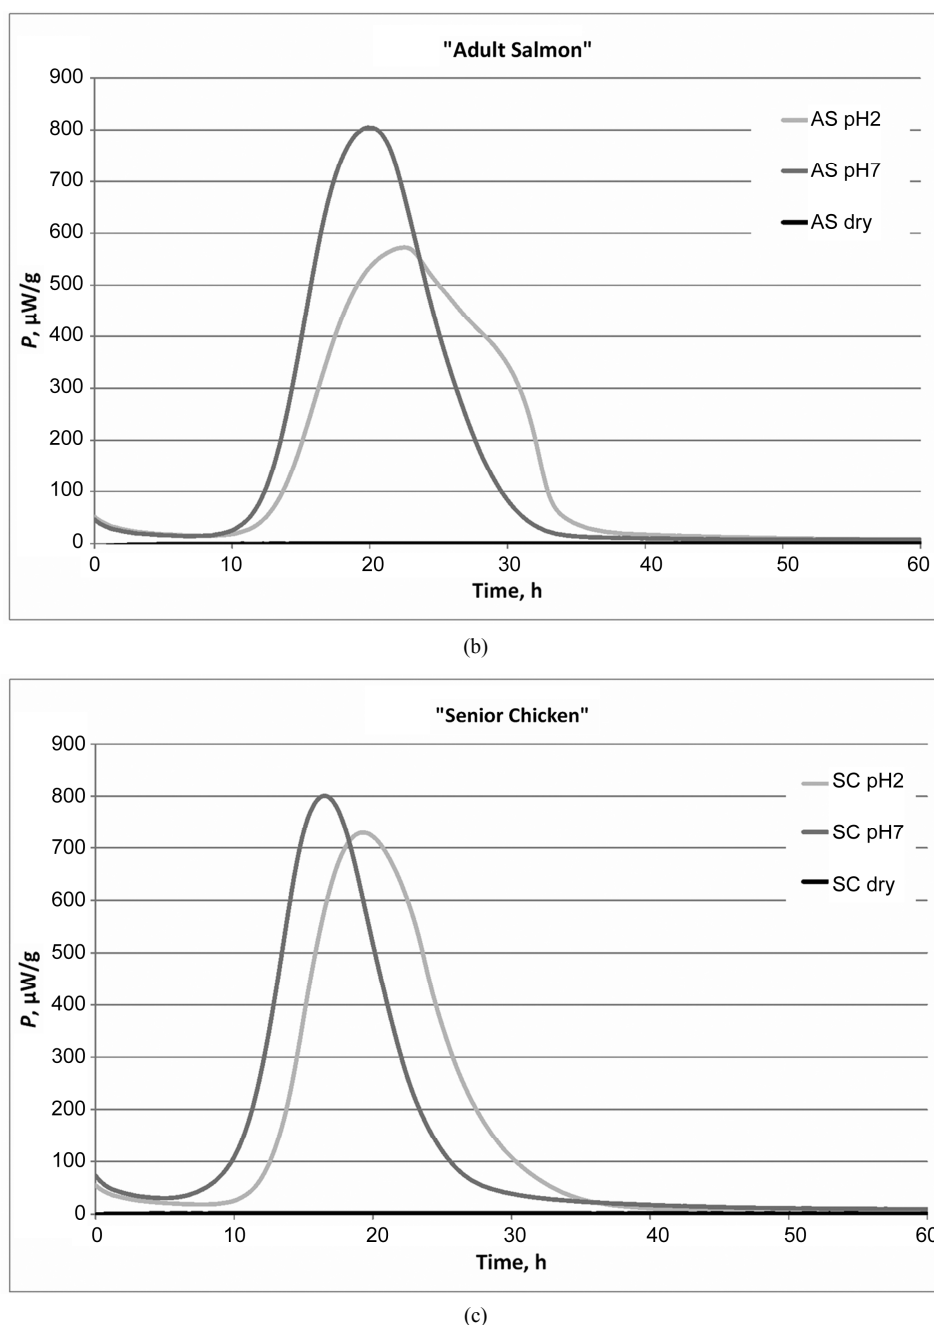

Power-time curves were analyzed according to the Kabanova [9] and all numerical values of processed power-time curves are presented in **Table 1**.

The length of the lag phase was  $3.9 \pm 0.72$  hours (in average) at pH 7 (neutral pH). The lag phase was prolonged by 1 hour, up to  $4.9 \pm 0.2$  hours (in average) at pH 2 (low pH), which is the pH level in the stomach of dogs [13]. Prolongation of the lag-phase at low pH can be explained by acidic stress effect on the probiotic bacteria.

The average specific maximum growth rate ( $\mu_{\max}$ , W/h) of the *Enterococcus faecium* bacteria was practically the

(a)

**Figure 1. Power-time curves of growth of probiotic bacteria in three different dog food: dry and moisturized samples (AC, AS and SC) at two different pH (pH = 2 and pH = 7) values.**

same at low and neutral pH levels ( $0.5209 \pm 0.0634$  W/h and  $0.5391 \pm 0.0539$  W/h correspondingly).

The average heat produced during the exponential phase ( $S_{\text{exp}}$ , J/g) at neutral pH was  $15.33 \pm 0.90$  J/g and  $13.67 \pm 0.74$  J/g at acidic pH condition. Using the  $Y_Q$  value  $2.58 \pm 0.44 \times 10^{-9}$  J/cfu determined by us for *L. lactis* IL1403 [10] the average number of bacteria grown during the exponential growth ( $N_{\text{exp}}$ , cfu/g— $5.93 \times 10^9$  cfu/g at neutral pH and  $5.29 \times 10^9$  cfu/g at low pH) was calculated—see **Table 1**.

The estimates of biomass obtained should be considered reliable, as the values of  $Y_Q$  have been practically the same in the different papers:  $5.53 \times 10^{-8}$  J/cfu for soil samples [21],  $4.22 \times 10^{-9}$  J/cfu and  $3.4 \times 10^{-8}$  J/cfu for *Staphylococcus aureus* and *E. coli* respectively [22].

The total heat produced during the entire period of thermodynamic activity (full length of power-time curves registered, all bacteria growth phases included  $S_{\text{tot}}$ , J/g) was also practically the same at both pH-s studied. The average total heat produced at neutral pH was  $35.92 \pm$

**Table 1. Parameters describing bacterial growth of three dog food formulations (AC, AS, SC) at two different pH (pH = 2 and pH = 7) levels obtained from the processed power-time curves: lag phase duration ( $\lambda$ , h), maximal specific growth rate ( $\mu_{\max}$ , W/h), heat produced during exponential growth phase ( $S_{\exp}$ , J/g) and during the total growth ( $S_{\text{tot}}$ , J/g) and the respective numbers of bacteria produced during the both growth phases ( $N_{\exp}$ , cfu/g and  $N_{\text{tot}}$ , cfu/g respectively).**

		$\lambda$ , h	$\sigma$ , h	$\mu_{\max}$ , W/h	$\sigma$ , W/h	$S_{\exp}$ , J/g	$\sigma$ , J/g	$N_{\exp}$ , cfu/g	$S_{\text{tot}}$ , J/g	$\sigma$ , J/g	$N_{\text{tot}}$ , cfu/g
pH 2	AC	4.94	0.77	0.4547	0.05	14.28	0.86	5.53E+09	37.09	8.58	1.44E+10
	AS	5.08	0.49	0.5271	0.01	13.89	4.96	5.38E+09	32.18	7.77	1.25E+10
	SC	4.68	0.39	0.5809	0.00	12.85	0.92	4.97E+09	32.37	1.74	1.25E+10
pH 7	AC	3.54	0.33	0.5039	0.03	17.24	1.13	6.67E+09	41.62	3.78	1.61E+10
	AS	4.73	0.09	0.6012	0.04	15.52	1.11	6.01E+09	34.45	2.10	1.33E+10
	SC	3.42	0.50	0.5123	0.17	13.21	0.47	5.11E+09	31.68	3.40	1.23E+10

0.78 J/g and  $33.88 \pm 1.23$  J/g at low pH, which correspond to  $1.39 \times 10^9$  cfu/g and  $1.31 \times 10^9$  cfu/g respectively. The numbers of bacteria grown during the exponential growth phase ( $N_{\exp}$ , cfu/g) and bacteria grown during the complete growth ( $N_{\text{tot}}$ , cfu/g) achieved the same levels of  $10^9$  and  $10^{10}$  cfu/g correspondingly at the two pH values.

All three formulations of ProBiotic LIVE dog food (AC: Adult Chicken & Rice, AS: Adult Salmon & Rice and AS: Senior Chicken & Rice) enriched with probiotic bacteria of *Enterococcus faecium* (NCIMB10415) had the same initial bacterial count in average  $10^6$  cfu/g confirmed by *outplating* of the samples on the PCA presented in **Table 2**. Average concentration of bacteria in all the three dog food formulations was  $2.86 \times 10^6 \pm 5.31 \times 10^5$  cfu/g according to the results presented in **Table 2**. This confirms the claimed by a producer average *E. faecium* load of  $10^6$  cfu per gram in the product.

It is known that the low acidic pH in the stomach of dogs is considered as a barrier for the probiotic bacteria. Ability to preserve the viability during the passage through the stomach acidic barrier is a prerequisite for the further successful colonization of the host intestine by the probiotic bacteria. The *Enterococcus faecium* bacteria present in the dog food of ProBiotic LIVE formulations were able to show strong metabolic activity at low acidic pH value, which confirmed the fact that *Enterococcus faecium* can tolerate the passage through the acidic barrier of the dog's stomach and populate the intestine afterwards. The ability of the probiotic bacteria *Enterococcus faecium* (NCIMB10415), to preserve the activity throughout the passage through the stomach acidic barrier of dogs was also confirmed in the trials of the European Food Safety Authority (EFSA, [23]). Analysis of the power-time curves revealed that the duration of the time needed for the probiotic bacteria to regain their activity in the host organism after consumption, the length of the lag-phase, was about 5 hours (see **Table 1**). This time is sufficient for the digest flow to pass the acidic barrier of stomachs of dogs.

**Table 2. Plate counts of the bacteria on PCA and pH values of different dog food formulations and bacteria concentrate.**

Sample	$N$ , cfu/g	$\sigma$ , cfu/g	Bulk pH
AC	2.35E+06	2.19E+04	5.77
AS	3.41E+06	6.17E+04	5.87
SC	2.82E+06	5.14E+04	5.94
Bact. concentrate	2.24E+10	3.28E+08	5.23

There was no bacterial metabolic activity observed in the case of non-diluted dry dog food samples analyzed, see **Figure 1**. Also the freeze-dried *Enterococcus faecium* (NCIMB10415) bacteria powder concentrate (both dry and diluted samples) showed no thermal activity (data not shown).

#### 4. Conclusions

The results obtained showed clearly the ability of the probiotic *Enterococcus faecim* (NCIMB10145) bacteria strain present in the extruded dog food kibbles to preserve its viability and growth characteristics at acidic and neutral pH. This indicated that the extruded kibbles containing *E. faecium* bacteria are able to tolerate the dog's stomach acidic barrier with further successful colonization of the dog's intestine.

The results obtained showed that calorimetric technique is a prospective and sensitive method for the continuous *in-situ* monitoring of bacterial activity in such complicated matrices as extruded feed or food products, and for shelf-life determination of probiotic ingredients in the products.

#### 5. Acknowledgements

This investigation was financially supported through the grant ETF9192 of Estonian Science Foundation, through the grant SF0140090s08 of Estonian Ministry of Education and Research, and by the European Regional Development Fund project EU29994.

The authors wish to thank the Probiotics International Ltd. (UK) for providing the sample of the bacteria concentrate and Bacterfield S.A. (Luxembourg) for providing the dog food samples.
