Abstract

We provide a list of bird species for Ribeira lagoon, a protected area in Rio de Janeiro, southeastern Brazil. Data were obtained in monthly surveys in points along a continuous transect, between August 2008 and July 2009, and 21 ad libitum observations. In total, 174 species were listed, including 121 land birds and 53 waterbirds. Of these, 11 are considered threatened at regional level. Waterbird richness was significantly higher in the dry season (April to September) than in the rainy season (October to March), whereas land bird richness remained constant. However, land bird richness varied throughout the year, with the highest value in February 2009 (77 species) and the lowest in May 2009 (41 species). The species listed account for 23% of the total of 745 bird species listed for Rio de Janeiro, and for 49% of 108 waterbirds recorded for the state.

Keywords

Bird Richness; Neotropical Coastal Lagoons; Northern Rio de Janeiro; Restinga de Jurubatiba; Threatened Wetlands

1. Introduction

The Atlantic Forest biome is a priority area for global biodiversity concerns [1]. Within this biome, some of the most productive ecosystems worldwide can be found, including coastal lagoons [2], whose importance for waterbird conservation is recognized at regional and global levels [3]-[5]. Nevertheless, compared to other ecosystems, coastal lagoons are more consistently and intensely exposed to degradation [6] [7]. Also, the avifauna of coastal lagoons associated with the Atlantic forest biome has been poorly studied both in Brazil as a whole and in

*Corresponding author.

Rio de Janeiro state, where most currently published studies are focused on the city of Rio de Janeiro, the state's capital. This scenario becomes worse in northern Rio de Janeiro state, where Pacheco *et al.* [8] and Tavares *et al.* [9] pointed to a wide gap in ornithological knowledge. In spite of the lack of data on bird assemblages in northern Rio de Janeiro, few historically important studies have reported pertinent information on birds in the region [10]-[13].

Located in northern Rio de Janeiro, Ribeira lagoon is a coastal water body recently recognized as an Area of Environmental Protection (APA). However, no management plan has been developed for this lagoon, and it has not been studied in detail. This study aims to: 1) provide an inventory of birds recorded in Ribeira lagoon along a year of systematic surveys and additional data collected during opportunistic observations; 2) test if the richness of land and waterbirds differ significantly between the dry and rainy seasons and throughout the year.

2. Materials and Methods

2.1. Study Area

The present study was conducted in Ribeira lagoon (22°07'12" S; 41°27'03" W), located in Quissamã, a municipality in northern Rio de Janeiro, southeastern Brazilian coast. The study site is a 4 km² coastal lagoon surrounded by marshes and mudflats which may reach 30 km² during the rainy season (Figure 1). A few remnants of "Restinga" vegetation Forest still exist, but they make up about 2.5 km² of the study area. Restinga vegetation is described as mosaics of coastal plant communities under high fluvio-marine influence, which are included in Atlantic Forest biome [14]. Although Ribeira lagoon is a protected area, cattle ranching have been expanding steadily in recent years. Presently, about 10% of its total area (enhanced during the rainy season) is occupied by pastures. Also, this lagoon is located 8 km away from the Atlantic Ocean coast and is 2 km distant from Restinga de Jurubatiba National Park. Besides that, it communicates with Feia lagoon, the second largest freshwater lagoon of Brazil, through a mechanical floodgate. Climate in the region has two periods, the dry season (be-

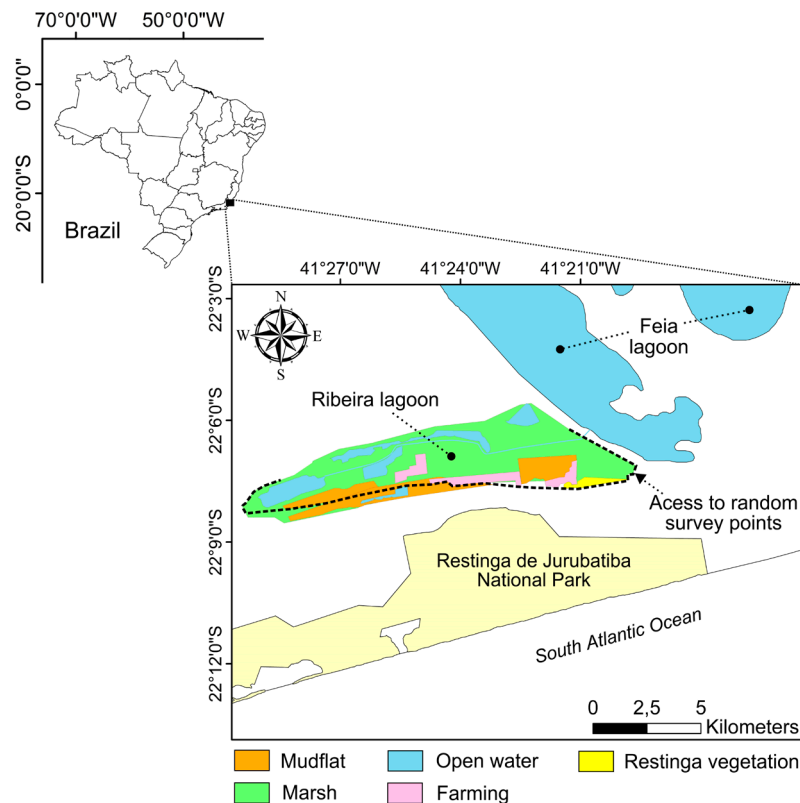

Figure 1. Location of Ribeira lagoon, in northern Rio de Janeiro State, southeastern Brazilian coast.

tween April and September) and the rainy season (between October and March) [15] [16].

2.2. Field Surveys

We carried out monthly excursions in Ribeira lagoon, between August 2008 and July 2009, comprising one complete cycle of climatic seasons and totaling 292 h of sampling efforts. Each monthly visit lasted three days. Surveys of species presence were conducted mainly between 6 am and 10 am, and 3 pm and 7 pm. More specifically, our observations were made along 20 semi-random points spaced by at least 300-m intervals along a linear transect around the lagoon. We called this “semi-random” sampling, because points were randomly chosen only in accessible locations [17]. Each point covered a circular area with a 300-m radius. The aim was to guarantee that species would be evenly detected across samples [18]. In addition, we conducted 21 *ad libitum* observations between November 2010 and May 2013, in order to complement the species’ list. This afforded 139 h of sampling efforts. The birds were observed with 8x42 binoculars and a (20 - 60) × 80 spotting scope.

2.3. Data Analysis

Differences in richness between dry and rainy seasons were assessed with the Mann-Whitney test for median comparison. We also used the chi-squared test to observe if richness varied significantly among months [19]. The species accumulation curve was obtained by the Jackknife 1 estimator, considering 10,000 randomizations without replacement, using data from August 2008 to July 2009. It should be mentioned that this estimator is suitable for this study design, because it allows working with incidence-based data, since we did not consider abundance data [20]-[22]. Statistical analyses were performed using R 3.0.0 [23].

3. Results

We recorded 174 bird species during visits in Ribeira lagoon, including 53 waterbirds and 121 land birds. Of these, 14 bird species were documented exclusively during *ad libitum* observations. The families with high numbers of species were Tyrannidae (18), Ardeidae (12) and Emberizidae (11). Additionally, of the 174 bird species, 13 (7.5%) were long-distance migrants, of which 12 are from the Northern Hemisphere and only *Tachycineta leucopyga* (Figure 2(B)) is from southern areas of South America (Appendix 1). Also, of a total of 13 migrants, seven were Nearctic Shorebirds (53.8%).

Interestingly, 11 of the species recorded are considered threatened (or near/probably) in Rio de Janeiro: *Dendrocygna bicolor*, *D. autumnalis*, (Figure 2(A)) *Cairina moschata*, *Sarkidiornis sylvicola*, *Platalea ajaja*, *Ciconia maguari*, (Figure 2(F)) *Himantopus melanurus* (Figure 2(D)), *Chroicocephalus cirrocephalus*, *Amazona rhodocorytha*, *Mimus gilvus* and *Sporophila collaris* (Figure 2(C)). In addition, *A. rhodocorytha* is considered threatened at both national and global levels.

With respect to the temporal variation in species richness, the observed monthly richness varied significantly for land birds ($\chi^2 = 36.6$, $P = 0.00021$), but not for waterbirds ($\chi^2 = 12.6$, $P = 0.32$). On the other hand, median values of waterbird richness were higher in the dry season (25 species) than in the rainy season (16 species) (Mann-Whitney test, $P = 0.004$), in contrast to the lack of difference for land birds (Mann-Whitney test, $P = 0.62$). The highest richness of land birds occurred in February 2009 (77 species), while the lowest value was observed in May (41 species). Moreover, the highest richness of waterbirds occurred in September 2008 (30 species), whereas the lowest was recorded in December 2008 and January 2009 (16 species each) (Appendix 1).

The rarefaction accumulation curve reached a clear asymptote after 12 monthly surveys. The Jackknife 1 index estimated the number of species at 183 ± 6 (Figure 3).

4. Discussion

Regarding temporal variation, the high richness of waterbirds in the dry season may be due to high availability of shallow waters, which are an advantageous feature considering the feeding habits of many species that occur exclusively during this season [24] [25]. These species include *Netta peposaca*, *D. bicolor*, *Tigrisoma lineatum*, *Ixobrychus involucris*, *Egretta caerulea*, *P. ajaja*, *Pandion haliaetus*, *Gallinula melanops*, *Calidris melanotos*, *Phalaropus tricolor* and *Chroicocephalus cirrocephalus*. In fact, during the dry season, water levels fall and the coastal lagoons of the region actually become pools, in a process whose results include the increase in concen-

Tavares, except *F. albiventer* by Gustavo Henrique.

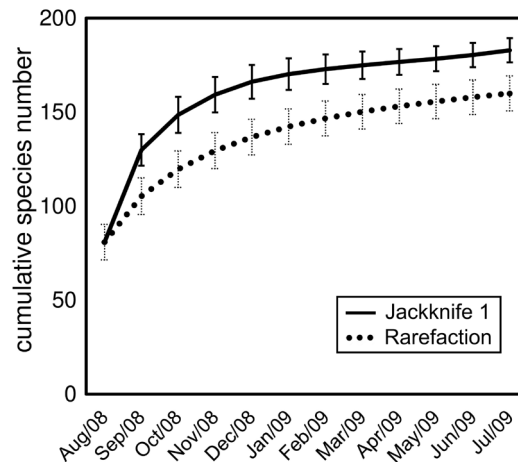

Figure 3. Accumulation curve of bird species recorded in Ribeira lagoon, northern Rio de Janeiro.

trations of preys consumed by waterbirds [9] [16] [26]. On the other hand, non-significant differences in species richness have been observed in other coastal wetlands of southeastern Brazil [27]-[29]. Yet, Ribeira lagoon features high environmental heterogeneity, similarly to the mosaic of wetlands located in Brazilian Pantanal [30] and in Rio Grande do Sul State [31]. So, the temporal changes in environmental characteristics in the site surveyed in the present study may be regarded as more remarkable, when compared to the homogeneous wetlands in southeastern Brazil [27] [28]. Interestingly, Fieker *et al.* [32] found higher richness of waterbird species during the rainy season, but in grasslands that become much drier in the dry season and therefore do not provide suitable habitats for waterbirds, differently from what was observed in Ribeira lagoon. All in all, the seasonal patterns found in the present study highlight the influence of rainfall in waterbird assembly structure in coastal lagoons in southeastern Brazil.

With respect to land birds, temporal variation occurs to a different scale. Variation takes place on a monthly basis, not between climatic seasons, indicating the intense species turnover in land bird assembly through the year. Thus, future monitoring in the region should be based on surveys carried out on a time basis, at monthly intervals, at least. Differently from our findings, Alves and Pereira [27] reported higher land birds richness during the rainy season and interpreted this difference as result of high availability of insects during this period. In Ribeira lagoon, differences in land bird richness may vary monthly simple because variation in food availability

(insects and fruits) follows the same time pattern. However, no data about invertebrate and fruit abundance for lagoons in northern Rio de Janeiro are available to allow testing this hypothesis. Further studies considering the role of environmental factors in land birds movements and trade-off in wetlands in northern Rio de Janeiro may contribute to clarify the seasonal richness pattern. In the meantime, we cannot rule out the possibility that one single year-based systematic survey did not suffice as an effort to detect seasonal land bird patterns across different rainfall regimes. Because of interannual variation in richness patterns, long-term data are very important in this sense, as observed for other areas in Brazil [29] [33] [34].

Some species previously listed for nearby wetlands were not recorded in our study. *Anas discors*, a migrant species from North America, was recorded by Antas *et al.* [13] in Feia lagoon. These authors and Sick [35] listed *Nycticryphes semicollaris* in Feia lagoon, while Tavares and Siciliano [5] reported the occurrence of this species in a coastal lagoon near Restinga de Jurubatiba National Park, suggesting that it is a resident in the region. We did not record *N. semicollaris* during our surveys, probably due to the cryptic habits of this species. Also, differently from what we expected, *Tangara peruviana* was not recorded in Ribeira lagoon, although it has been very active during the winter in Restinga de Jurubatiba National Park [36]. So, *A. discors*, *N. semicollaris* and *T. peruviana* could probably occur in Ribeira lagoon, because of its connectivity with Feia lagoon and areas of the Restinga de Jurubatiba National Park.

The richness predicted by the Jackknife 1 estimator (183 ± 6 species) was slightly greater than the value observed based on both systematic and ad libitum surveys together (174 species). This result reveals the high efficiency of this estimator, considering the sampling methods in the present paper. So, this estimator can be considered a useful tool to compare richness between wetlands surveyed according to different sampling efforts [22] [37]. However, comparisons of this nature are not possible, because the inventories made in similar areas in Rio de Janeiro state do not present species accumulation curves.

Our results can be compared with the information available for the Restinga de Jurubatiba National Park ($22^{\circ}12'03''$ S; $41^{\circ}28'04''$ W), the most similar environment recently inventoried. Alves *et al.* [36] compiled 96 species in this 680 km² protected area with 19 coastal lagoons [38]. In terms of waterbirds, 12 species were listed for Restinga de Jurubatiba and only *D. viduata* was mentioned as representative of the Anatidae family. Similarly, only 84 land birds were recorded in Restinga de Jurubatiba. Furthermore, the number of threatened species was higher for Ribeira lagoon (11 species, 6.3% of the total) than for Restinga de Jurubatiba (2 species, 2.1% of the total). Nevertheless, a recent continuous and systematic bird monitoring conducted in Restinga de Jurubatiba has found high richness and abundance of migratory and threatened species in Rio de Janeiro state [5]. In addition, *Mycteria americana* was recently recorded in a lagoon inside Restinga de Jurubatiba [39]. Thus, the differences in richness between the two areas are possibly due to low sampling effort conducted in lagoons where access is difficult in Restinga de Jurubatiba, by Alves *et al.* [36]. Long-term data are necessary to afford a more accurate comparison between these areas.

When compared to other lowlands exhaustively inventoried in Rio de Janeiro state, Ribeira lagoon shows higher richness. For example, a recent study in 3.80 km² of lagoons, marshes and forest in Jacarepaguá lowlands ($22^{\circ}58'53''$ S; $43^{\circ}22'27''$ W) listed 142 bird species, in contrast with the 172 recorded in Ribeira lagoon [40]. Besides that, Rodrigo de Freitas lagoon ($22^{\circ}58'22''$ S; $43^{\circ}12'43''$ W) presented only 31 species [27]. This significantly lower richness reflects the high degree of environmental degradation and long-lasting anthropogenic influence in natural hydrological conditions of wetlands of central coast of Rio de Janeiro, in comparison with wetlands in the north of the State.

Regarding the occurrence of threatened birds in the study site, *Dendrocygna autumnalis* was previously reported by Antas *et al.* [13] for Feia lagoon, although a few records were made in the central coast of Rio de Janeiro, an extensively surveyed region [41]–[43]. In the present study, this species was recorded in 92% of surveys and in flocks of up to 300 individuals. These findings confirm a recent geographic expansion of *D. autumnalis* in Rio de Janeiro [42], and highlight the need for the adoption of conservation strategies for Ribeira lagoon. *Dendrocygna bicolor* is rare in the state, though it has been recorded in the municipality of Rio de Janeiro [44]; however, it was never recorded in northern Rio de Janeiro. Low numbers of *Sporophila collaris* were observed in the Poço das Antas Biological Reserve, Silva Jardim [45], but this species was frequently recorded in the marsh vegetation dominated by *Typha domingensis* in Ribeira lagoon. Interestingly, *C. maguari*, *M. americana* and *C. moschata*, which are considered extinct in the municipality of Rio de Janeiro [46], were recorded in the study site. It should be emphasized that remnants of natural wetlands in northern Rio de Janeiro, such as Ribeira lagoon, may represent remarkable habitat remnants for *D. bicolor*, *D. autumnalis*, *C. maguari* and *S. collaris*,

whose populations are under threat at state level [26] [47].

Of the total number of species recorded, *Passer domesticus*, *Estrilda astrild* and *Cariama cristata* were introduced. The first two originate from the European and African continents, and were introduced in Brazil in the early 1900's, expanding their distribution ranges using their forage and reproductive skills [48]. The third descends from individuals introduced in the Restinga de Jurubatiba National Park by farmers [49]. Also, *Paroaria dominicana*, typical of the dry Caatinga biome, was probably introduced due to traffic, as observed in other areas in Brazil [50]-[52]. On the other hand, some relatively recent cases of invasive species [53] in Ribeira lagoon are noteworthy: *Bubulcus ibis*, *Herpetotheres cachinnans*, *Patagioenas picazuro*, *Mimus saturninus*, *Paroaria dominicana*, *Fluvicola nengeta*, *Fluvicola albiventer* (Figure 2(D)) and *Theristicus caudatus*. *Bubulcus ibis* is native to the African continent [54], and its first record in Brazil was made in 1964 by Sick [55], when it started to expand its distribution range, using pastures. Both *F. nengeta* and *F. albiventer* inhabit wet environments associated with open areas [51]. The first is expanding its geographic range towards the south Brazil, benefiting from the expansion of open areas due to deforestation [50], and seems to have colonized Rio de Janeiro around the 1950's [44]. The second occurs in large river basins, mainly in northeastern Brazil, Minas Gerais, Paraná and São Paulo states. Until recently it was presumed that the species did not occur in the states of Espírito Santo and Rio de Janeiro, with a spatial gap between Bahia and São Paulo [56]. However, the present record, made on the 3rd of May 2010, together with the breeding report in a lagoon in "Campos dos Goytacazes" [57], suggests that this species may be expanding its range in Rio de Janeiro in response to forest clearing. The record of *Theristicus caudatus* represents a special case of rapid colonization of open areas in the State, possibly due to deforestation [58].

The documented record of *T. leucopyga* represents the first for Rio de Janeiro state, and prompted the inclusion of this species in the bird list of the state [59]. On the 11th of August 2008, a large flock of about 6000 swallows was sighted flying and roosting on the banks of the lagoon. Likewise, at least 2000 individuals were recorded on the 18th of June 2009. Although it is known that *T. leucopyga* breeds from Chile to Argentina and moves to Brazil during the winter [56], few records of the species in coastal areas of the country have been published.

The list of species we have provided for Ribeira lagoon includes 23% of the total of 745 bird species listed for Rio de Janeiro, as well as 49% of 108 inland waterbirds recorded for the state. In this context, the high number of species recorded, besides the eleven threatened species at state level (nine waterbirds), highlights the importance of this natural wetland. Yet, Ribeira lagoon is under intense pressure due to the digging of canals to claim land for agriculture, sewage discharges, hunting and human-induced fire, such as observed in other lagoons in northern Rio de Janeiro. Thus, further studies should evaluate waterbirds habitat use in this coastal lagoon and other similar environments, in order to improve restoration and management strategies.

Acknowledgements

The authors are grateful to the municipal authorities of Quissamã and ICMBio and to the Ecology and Natural Resources Post-graduation Program, State University of Northern Rio de Janeiro. Also, authors thank to J.F. Pacheco for kindly providing relevant literature; to A.B.A. Soares for helpful comments on the study and to G. Brito and A. Zillikens for reviewing early versions of the manuscript. This study is part of the wetland birds monitoring program in the northern coast of the Rio de Janeiro State. S. Appendix 1

Appendix 1. Birds recorded in Ribeira lagoon, northern Rio de Janeiro, southeastern Brazil. **Legend.** Regional threat status (RJ, Alves *et al.* 2000): Ne = near (or probably) endangered, Vu = vulnerable and En = endangered. Group: W = Waterbirds, L = Land birds. Migratory status: VN = Nearctic migrant, VS = Southern migrant and R = Resident. The circles indicate the presence of species in each month during systematic surveys and triangles indicate species recorded only during ad libitum surveys. Grey area indicates the rainy season. Taxonomy follows the Brazilian Committee of Ornithological Records [60].
