## ABSTRACT

Estimation of the volume of information in black holes is necessary for generation of restrictions for their formation, development and interconversion. Information is an integral part of the Universe. By its physical essence information is heterogeneity of matter and energy. The universal measure of physical heterogeneity of information is the Shannon information entropy. It is important to note that the Neumann entropy cannot be applied as the universal measure of heterogeneity because it is equal to zero for structured pure state. Therefore information is inseparably connected with matter and energy. The informatics laws of nature are: the basic law of Zeilinger's quantum mechanics postulates that the elementary physical system (in particular, fundamental particles: quarks, leptons,...) bears one bit of information, the law of simplicity of complex systems, the law of uncertainty (information) conservation, the law of finiteness of complex systems characteristics, the law of necessary variety by W. Ashby, and the theorem of K. Gödel. The law of finiteness of complex systems characteristics and the principle of necessary variety by W. Ashby impose restrictions on the topology and symmetry of the universe. The author's works testify about the practicality of information laws simultaneously with physical rules for cognition of the Universe. The results presented in this paper show the effectiveness of informational approach to studying the black holes. The article discusses the following questions: The volume of information in the black hole, Emission and absorption of usual substance by a black hole, Formation and development (changing) of black holes, Black hole merger. Black hole is called optimal if information content is minimal at the University region. Optimal black holes can exist when at least the two types of substance are available in the Universe: with non-linear and linear correspondence between information content and mass. Information content of optimal black hole is proportional to squared coefficient correlating information content with mass in usual substance and in inverse proportion to coefficient correlating information content with black hole mass. Concentration of mass in optimal black hole minimizes information content in the system "usual substance—black holes". Minimal information content of the Universe consisting of optimal black holes only is twice as less as information content available of the Universe of the same mass filled with usual substance only. An information approach along with a physical one allows obtaining new, sometimes more general data in relation to data obtained on the ground of physical rules only.

**Keywords:** Black Holes; Usual Substance; Information; Models; Volume; Restrictions; Universe

## 1. Introduction

Estimation of the volume of information in cosmological objects, including stars of the Sun type, neutron stars, white dwarfs and black holes, is necessary for generation of restrictions for their formation, development and interconversion. Information is an integral part of the Universe. The basic law of Zeilinger's quantum mechanics postulates that the elementary physical system (in particular, fundamental particles: quark, electron, photon) bears one bit of information. By its physical essence information is heterogeneity of matter and energy. Therefore information is inseparably connected with matter

and energy. An information approach along with a physical one allows obtaining new, sometimes more general data in relation to data obtained on the ground of physical rules only. Information is inextricably linked with matter and energy. The universal measure of physical heterogeneity of information is the Shannon information entropy. It is important to note that the Neumann entropy cannot be applied as the universal measure of heterogeneity because it is equal to zero for structured pure state. Use of the information approach, along with the physical, provides a new and sometimes more general information in relation to the information obtained on the basis of

only physical laws. The author's works, testify about the practicality of information laws simultaneously with physical rules for cognition of the Universe. The estimates cited below are based on the foundational principle of Zeilinger quantum mechanics *i.e.* "an elementary system carries one bit of information" and prove it. The elementary systems are fundamental particles (quarks, leptons, photons).

## 2. The Informatics Laws of Nature

The informatics laws of nature are [1-3]:

**The main principle of quantum mechanics by A. Zeilinger:** *Elemental physical systems contain (carry) one bit of information.*

**The law of simplicity of complex systems.** *Such variant of complex system is realized, survives which possesses the minimum complexity.*

The law of simplicity of complex systems is realized by nature in a number of constructive principles:

"Occam Razor"; hierarchical modular construction of complex systems; symmetry; simmorfoz, stability; field interaction (interaction through the carrier or interactions through space-time status, for example, curvature of space-time); extreme uncertainty (functions of characteristics distribution have extreme uncertainty).

**The law of conservation of uncertainty (information).** *Uncertainty (information) of the isolated (closed) systems is saved at physically realized transformations and only at physically realized transformations.*

**The law of finiteness of information characteristics of complex systems.** *All kinds of interaction between systems, their parts and elements have final speed of distribution. Speed of change of system states of elements is limited also.*

In any system of coordinates information on event is always final. Duration of signal  $\Delta T$  is always more than zero ( $\Delta T > 0$ ). Information on coordinates of physical systems in our Universe is limited by 333 bits.

**The law of necessary variety by W. Ashby.** *For effective functioning of system a variety of operating body should no be less then variety of management object.*

Uncertainty (information) is the basic characteristic of a variety of systems. The law of necessary variety by W. Ashby is also realized in a number of concrete principles:

Shannon theorems, Kotelnikov theorem, Kholevo theorem, Brillouin theorem, theorem of Margolis-Levitin.

**Gödel theorem of incompleteness.** *In enough rich theories (containing on arithmetic) there are always the unprovable true assertions.*

**The law of systems complexity growth.** *During systems evolution its uncertainty (systems information) grows.*

**Le Chatelier Principle.** *External influence discompos-*

*ing system, calls in it the processes, aspiring to weaken results of this influence.*

## 3. The Volume of Information in the Black Hole

The basic law of Zeilinger's quantum mechanics postulates that the elementary physical system (in particular, fundamental particles: quark, electron, photon) bears one bit of information [1]. The volume of information in physical systems is estimated the information entropy [4,5]. The information volume of a black hole of mass

$M_{\text{ch}}$  is equal to  $I_{\text{Bh}} = \frac{2\pi \cdot G}{\hbar \cdot c} M_{\text{Bh}}^2$  nat, or

$I_{\text{Bh}} = \frac{2\pi \cdot G}{\hbar \cdot c \cdot \ln 2} M_{\text{Bh}}^2$  bit [6,7]. The information volume

contained in the black hole is proportional to its squared mass. How to explain it? Let us assume that a black hole contains  $n$  pairwise interacting particles (q-bits). Then the quadratic dependence of the volume of information in the black hole on its mass can be explained by the fact that each interaction forms 1 bit of information. The black hole is described with the wave function

$\psi_n = \frac{1}{\sqrt{2}}(|0_1\rangle|0_2\rangle \cdots |0_n\rangle + |1_1\rangle|1_2\rangle \cdots |1_n\rangle)$ . As mentioned

earlier the volume of information in the system described with the present given function is equal to

$I_n = \frac{n \cdot (n+1)}{2}$  bit. At  $n \gg 1$  the volume of information

in the black hole is proportional to the black hole squared mass  $I_n \approx \frac{n^2}{2}$ . A black hole consisting of  $n$  particles

contains the information, which is  $n$  bit larger than a black hole consisting of  $n-1$  particles:

$$I_n - I_{n-1} = \frac{n(n+1)}{2} - \frac{(n-1) \cdot n}{2} = n.$$

Let us compare the estimates of squared mass of a black hole:  $M_{\text{Bh}}^2 = \frac{\hbar \cdot c \cdot \ln 2}{2\pi \cdot G} \cdot I_{\text{Bh}}$  (from cosmological

formula [6-8]) and  $M_{\text{Bh}}^2 = n^2 \cdot m_0^2$  (squared mass  $n$  of the particles composing the black hole). We have

$M_{\text{Bh}}^2 = n^2 \cdot m_0^2 = \frac{\hbar \cdot c \cdot \ln 2}{2\pi \cdot G} \cdot I_{\text{Bh}}$ . As far as  $I_{\text{ch}} = \frac{n^2}{2}$ , then

$$n^2 \cdot m_0^2 = \frac{\hbar \cdot c \cdot \ln 2}{2\pi \cdot G} \cdot \frac{n^2}{2}, \text{ or } m_0^2 = \frac{1}{4\pi} \cdot \frac{\hbar \cdot c \cdot \ln 2}{G}.$$

Eventually we obtain the estimate of mass of particles being part of the black holes:

$$m_0 = \frac{\sqrt{\ln 2}}{2\sqrt{\pi}} \sqrt{\frac{\hbar \cdot c}{G}} = \frac{\sqrt{\ln 2}}{2\sqrt{\pi}} \sqrt{\frac{h \cdot c}{2\pi \cdot G}} \text{ g, that agree by its}$$

magnitude with Planck mass  $m_{Pl} = \sqrt{\frac{\hbar \cdot c}{G}} \approx 2.17 \times 10^{-5} \text{ g}$  :

$$m_0 = \frac{\sqrt{\ln 2}}{2\sqrt{\pi}} m_{Pl} \approx 0.23 \sqrt{\frac{\hbar \cdot c}{G}} = 5.09 \times 10^{-6} \text{ g} .$$

Therefore, a black hole is the aggregate of particles (let us call them black particles) each having a mass equal to 0.23th of Planck mass) and interacting with all other black particles that form a black hole. Characteristics and models used in the paper are taken from [9-16] and [13-24].

#### 4. Emission and Absorption of Usual Substance by a Black Hole

Suppose that at the initial instant of time a black hole consisting of  $n$  black particles has the mass of

$$M_n = n \cdot m_0 \text{ and contains } I_n = \frac{n \cdot (n+1)}{2} \text{ bit of information.}$$

The black hole mass changes (increases or decreases) by black particles (quanta)  $\Delta M = m_0$ . As far as each black hole has the sub-Planck mass  $m_0$ , then the change in energy of a black hole in such a case is equal to  $\Delta E = m_0 c^2$ . In the event of the loss of emission of one black particle the mass of a black hole becomes equal to  $M_n = (n-1) \cdot m_0$ . In this case the volume of information remaining in the black hole is

$$I_{n-1} = \frac{(n-1) \cdot n}{2} \text{ bit. Change (loss) of information in the}$$

black hole comes to  $n$  bit.

For further estimates we implement the law of conservation of uncertainty (information) [2,3] and energy conservation principle. According to the law of conservation of uncertainty (information) a change in the system “a black hole with the mass  $M_n = n \cdot m_0$ —external environment” on emission of one black particle must be balanced by the occurrence of  $n$  particles containing 1 bit each:  $I_n - I_{n-1} = n$  bit. It can be believed that  $n$  photons of frequency  $\nu$  and energy  $h\nu$  emerged.

In virtue of energy conservation principle  $n \cdot h\nu = m_0 c^2$

and  $\nu = \frac{m_0 c^2}{n \cdot h}$ . Because  $m_0 = \frac{\sqrt{\ln 2}}{2\sqrt{\pi}} \sqrt{\frac{\hbar \cdot c}{G}}$ , then the

frequency of emitted photon must be equal to

$$\nu = \frac{1}{n} \cdot \frac{\sqrt{\ln 2}}{2\sqrt{\pi}} \sqrt{\frac{c^5}{\hbar \cdot G}} = \frac{4.34 \times 10^{42}}{n} 1/c . \text{ Because}$$

$$t_{Pl} = \sqrt{\frac{\hbar \cdot G}{c^5}} \approx 5.41 \times 10^{-44} c , \text{ then } \nu = \frac{1}{n} \cdot \frac{\sqrt{\ln 2}}{2\sqrt{\pi} \cdot t_{Pl}} . \text{ Let}$$

us denote  $\nu_0 = \frac{\sqrt{\ln 2}}{2\sqrt{\pi}} \frac{1}{t_{Pl}} = \frac{\sqrt{\ln 2}}{2\sqrt{\pi}} \sqrt{\frac{c^5}{\hbar \cdot G}} \approx 0.43 \times 10^{43} 1/c .$

Then  $\nu = \frac{\nu_0}{n}$ .

In the case of a black hole containing one black particle the radiation frequency is maximal and in inverse proportion to Planck time unit. Similar dependences are true for absorption of photons by black holes.

**Note 1.** In the general case, there must appear  $n$  photons having the frequency of  $\nu_i$  and aggregated energy

$$h \sum_{i=1}^n \nu_i = m_0 c^2 \text{ equal to } n \text{ bit.}$$

**Note 2.** In the general case, there must appear  $k$  particles with aggregated information equal to  $n$  bit and aggregated energy  $m_0 c^2$ .

**Note 3.** In the general case, there must be absorbed  $n$  photons having the frequencies  $\nu_i$  and the aggregated

$$\text{energy } h \sum_{i=1}^n \nu_i = m_0 c^2 \text{ equal to } n \text{ bit.}$$

**Note 4.** In the general case, there must be absorbed  $k$  particles with aggregated information equal to  $n$  bit and aggregated energy  $m_0 c^2$ .

Identical dependencies are true for cases when photons are absorbed by black holes. **In virtue of the law of conservation of uncertainty (information)**, the changes in the system “a black hole with the mass

$M_{n-1} = (n-1) \cdot m_0$ —external environment”, when the mass of a black hole is increased by the mass of one black particle, must be determined by absorption of  $n$  particles containing 1 bit each:  $I_n - I_{n-1} = n$  bit. Suppose that there had been absorbed  $n$  photons of frequency  $\nu$  and energy  $h\nu$ . **By virtue of energy conservation principle**  $n \cdot h\nu = m_0 c^2$ . The frequency of each absorbed photon must be equal to

$$\nu = \frac{1}{n} \cdot \frac{\sqrt{\ln 2}}{2\sqrt{\pi}} \sqrt{\frac{c^5}{\hbar \cdot G}} = \frac{4.34 \times 10^{42}}{n} 1/\text{sec} . \text{ At the formation}$$

of a black hole consisting one black particle the absorption frequency is maximal and inversely proportional to Planck time unit.

Having the estimates of black holes distribution by mass one can calculate the intensity of aggregated distribution of black holes radiation by frequencies and compare them with the experiment results. From the obtained radiation frequency expression one can draw the estimate of black hole radiation temperature. We calculate the temperature of the radiation of a black hole. The thermal radiation of a black body is related to the average energy

of radiation  $h\nu = 2.7kT$ , or  $T = \frac{h\nu}{2.7k}$ . Since

$$\nu = \frac{m_0^2 c^2}{M \cdot h} = \frac{\ln 2}{8\pi^2} \frac{c^3}{M \cdot G} , \text{ then}$$

$$T = \frac{h\nu}{2.7k} = \frac{h}{2.7k} \frac{\ln 2}{8\pi^2} \frac{c^3}{M \cdot G} = \frac{\ln 2 \cdot \hbar \cdot c^3}{4\pi \cdot 2.7 \cdot k \cdot M \cdot G} . \text{ The}$$

resulting estimate of temperature radiation from the black hole mass can be called information estimate of tem-

perature, which coincides up to a factor  $\frac{2 \ln 2}{2.7} \approx 0.51$

with an estimate of Hawking  $T_H = \frac{\hbar \cdot c^3}{8\pi \cdot k \cdot G \cdot M}$ .

### 5. Formation and Development (Changing) of Black Holes

Let us assume that a black hole of mass  $M_n = n \cdot m_0$  is formed from the usual substance (radiation). As mentioned earlier, such a black hole contains

$I = \frac{n(n+1)}{2}$  bit of information. Therefore, for its for-

mation are needed  $\frac{n(n+1)}{2}$  particles of usual substance

(radiation quanta), each of them containing 1 bit. For formation of a black hole of the mass equal to  $M$  kg it

is necessary to form  $n = \frac{M}{m_0}$  sub Planck particles and

use  $\frac{n(n+1)}{2} = \frac{M}{m_0} \left( \frac{M}{m_0} + 1 \right) \approx \frac{M^2}{2m_0^2}$  radiation quanta.

Thus, for formation of a black hole with the mass of the Sun equal to  $\approx 2 \times 10^{30}$  kg, it is necessary to form

$n = \frac{M_c}{m_0} = \frac{2 \times 10^{33}}{5 \times 10^{-6}} = 4 \times 10^{38}$  sub Planck particles and

use  $\frac{n(n+1)}{2} \approx 8 \times 10^{76}$  radiation quanta.

It is known that during supernova explosion the radiation energy is on the order of  $10^{50}$  erg, the maximum  $10^{54}$  erg. Whereas the average radiation frequency is  $10^{18}$  Hz, then the supernova explosion generates

$N = \frac{10^{50} (10^{54})}{10^{-27} 10^{18}} = 10^{59} (10^{63})$  radiation quanta. Assum-

ing that  $\approx 100\%$  radiation quanta is used for black hole formation, then the mass of a black hole would be equal to about

$M \approx \sqrt{2N} m_0 = 4.47 \times 10^{29} \times 5 \times 10^{-6} \approx 2.3 \times 10^{24}$  g.

The **Table 1** (columns 1 - 4) present information characteristics of black holes of different masses.

From the above chart it follows that:

- The mass of a black hole formed during the supernova explosion is close to the mass of an optimal black hole in the system “a black hole—radiation”. One can expect that during the supernova explosions the black holes be formed having the masses under which the information volume in the adjacent space is close to minimum.
- For formation of the black holes with the mass equal to million masses of the Sun the volume of information exceeding the volume of information of the Universe ( $10^{90}$  bit) is required [2,3,25]. Significant volumes of information are needed for formation of the black holes with the same mass as of the Sun’s. In

such case the volume of information of about  $10^{76}$  is required. It means that locally (in the zone of black hole formation) there must take place the intensive physical processes of radiation formation. For instance, the supernova explosions and accelerated motion of relativistic particles.

### 6. Black Hole Merger

Let us consider a system consisting of the two black holes. Suppose that the black holes have the mass of  $M_1 = n_1 m_0$ ,  $M_2 = n_2 m_0$  ( $m_0$ —the minimal black hole mass,  $n_1, n_2 = 1, 2, \dots$ ) and contain the volume of information equal to  $I_1 = \frac{n_1(n_1 + 1)}{2}$  and  $I_2 = \frac{n_2(n_2 + 1)}{2}$ .

The mass of the system is equal to  $M_{1+2} = (n_1 + n_2)m_0$ , the volume of information in the system is

$$I_{1+2} = \frac{n_1(n_1 + 1)}{2} + \frac{n_2(n_2 + 1)}{2}.$$

Is it possible that a black hole is formed as a result of the two given black holes merger and only two given black holes? The mass of a new black hole must be equal to the sum of the masses of

the original black holes  $M = M_{1+2} = (n_1 + n_2)m_0$ . The volume of information in the new black hole must be equal to  $I = \frac{(n_1 + n_2)(n_1 + n_2 + 1)}{2}$ . It is obvious that

under no masses of the original black holes the volume of information in the newly formed black hole would coincide with the total volume of information in the original black holes

$$I = \frac{(n_1 + n_2)(n_1 + n_2 + 1)}{2} = \frac{n_1^2 + n_1 n_2 + n_1 + n_1 n_2 + n_2^2 + n_2}{2} \\ \neq \frac{n_1^2 + n_1 + n_2^2 + n_2}{2} = \frac{n_1(n_1 + 1)}{2} + \frac{n_2(n_2 + 1)}{2} = I_1 + I_2.$$

Let us consider the following example. Suppose that the mass of the black holes is  $M_1 = M_2 = m_0$  and they contain the volume of information equal to  $I_1 = I_2 = 1$ . The mass of the system is  $M_{1+2} = 2m_0$ , the volume of information in the system is  $I_{1+2} = 1 + 1 = 2$ .

Is it possible that a black hole is formed as a result of merging the two black holes of the minimal mass and only the two given black holes of the minimal mass? The

mass of a new black hole must be equal to the sum of masses of the original black holes  $M = M_{1+2} = 2m_0$ . The volume of information in a new black hole must be equal to  $I = \frac{(1+1)(1+1+1)}{2} = 3$ . Apparently the volume of information in a new black hole does not coincide with the aggregated volume of information in the original black holes.

We give a system of equations for estimation of the mass of a black hole under formation when the two black holes are merged. Let us suppose that the black holes before merging possess the mass of  $M_1 = n_1 m_0$ ,  $M_2 = n_2 m_0$  ( $m_0 = 5.09E - 09$  kg — is the minimum mass of the black hole  $n_1, n_2 = 1, 2, \dots$ ) and contains the volume of information equal to  $I_1 = \frac{n_1(n_1+1)}{2}$  and

$I_2 = \frac{n_2(n_2+1)}{2}$ . As a result of the original black holes a black hole and usual substance are created. The mass of the black hole after the merger is equal to  $M_{1+2} = nm_0$ , the mass of information in the newly formed black hole is equal to  $I_{1+2} = \frac{n(n+1)}{2}$ . A number of particles of

usual substance that have been formed after the merger is equal to  $x$ . The volume of information in the usual substance is equal to  $I_{Us} = x$ . The average mass of a particle of usual substance is equal to  $m$ .

From the law of conservation of uncertainty (information) it follows:

$$I_1 + I_2 = \frac{n_1(n_1+1)}{2} + \frac{n_2(n_2+1)}{2} = \frac{n(n+1)}{2} + x$$

$$= I_{1+2} + I_{Us}.$$

We believe that the main energy of black holes and usual substance is concentrated in the mass. Then from the energy conservation principle it follows:

$$M_1 + M_2 = (n_1 + n_2)m_0 = nm_0 + xm.$$

1) Thus we have a two-equations system

$$\frac{n_1(n_1+1)}{2} + \frac{n_2(n_2+1)}{2} = \frac{n(n+1)}{2} + x,$$

$$(n_1 + n_2)m_0 = nm_0 + xm,$$

with three unknowns  $n, x, m$ .  $x \geq 0$ . Hence,

$$\frac{n_1(n_1+1)}{2} + \frac{n_2(n_2+1)}{2} \geq \frac{n(n+1)}{2},$$

or at  $n \gg 1$   $n^2 \leq n_1^2 + n_2^2$  (restriction on the mass of the black hole after merging).

2) Next we have

$$n_1^2 + n_1 + n_2^2 + n_2 - n^2 - n = 2x, \quad (n_1 + n_2)m_0 = nm_0 + xm.$$

3) And

$$x = \frac{n_1^2 + n_1 + n_2^2 + n_2 - n^2 - n}{2},$$

$$m = \frac{(n_1 + n_2 - n)m_0}{x} = \frac{2(n_1 + n_2 - n)}{n_1^2 + n_1 + n_2^2 + n_2 - n^2 - n} m_0.$$

4) At  $n \gg 1$   $m \approx \frac{2m_0}{n}$ .

The following assertions are valid.

**Assertion 1.** *A black hole cannot be created by means of merging the two black holes and only two black holes. Merging of black holes can occur only with the absorption and emission of usual substance.*

**Assertion 2.** *A black hole cannot be created by means of merging  $k$  black holes and only  $k$  black holes. Merging of black holes can occur only with extra absorption and emission of usual substance.*

**Assertion 3.** *A black hole can reduce its mass through emission of usual substance and only it into space. A black hole can increase its mass through absorption of usual substance and only it from space. During the two black holes merger one of them should emit usual substance into space while another one should absorb usual substance from space.*

**Assertion 4.** *During the merger of two black holes having the masses  $M_1 = n_1 m_0$ ,  $M_2 = n_2 m_0$ , without using any additional usual substance, the mass of a newly formed black hole is less than*

$M_{1+2} = \sqrt{n_1(n_1+1) + n_2(n_2+1)}m_0 \approx \sqrt{n_1^2 + n_2^2}m_0 = \sqrt{M_1^2 + M_2^2}$ . *During the merger of two black holes having the same masses  $M_1 = M_2 = nm_0$ , the mass of a newly formed black hole is less than*

$M_{1+2} = \sqrt{2n^2}m_0 = nm_0\sqrt{2} = \sqrt{2}M_1 = \sqrt{2}M_2$ . *The mass of a black hole that was formed as a result of the merger of 2 black holes of the same masses without using any additional usual substances is  $\sqrt{2}$  times less than the sum of masses of merging black holes. The remaining mass is dissipated in the space.*

**Assertion 5.** *During the merger of  $k$  black holes having the mass of  $M_i = n_i m_0$  without using any additional usual substance, the mass of a newly formed black hole is less than*

$$M_{1+2+\dots+k} = m_0 \sqrt{\sum_{i=1}^k n_i(n_i+1)} \approx m_0 \sqrt{\sum_{i=1}^k n_i^2} = \sqrt{\sum_{i=1}^k M_i^2}.$$

*During the merger of  $k$  black holes of the same masses  $M_i = nm_0 = M$  without using any additional usual substance, the mass of a newly formed black hole is less than  $M_{1+2+\dots+k} = \sqrt{kn^2}m_0 = nm_0\sqrt{k} = \sqrt{k}M$ . The mass of a black hole that was formed as a result of the merger of  $k$  black holes having the same masses is  $\sqrt{k}$  times less than the sum of masses of merging black holes. The remaining mass is dissipated in the space.*

**A system consisting of the two black holes and usual substance.** Let us consider a system consisting of the two black holes and usual substance. The black holes possess the same mass  $M_{1,0} = nm_0$ ,  $M_{2,0} = nm_0$  and contain the same volume of information  $I_{1,0} = \frac{n(n+1)}{2}$  and  $I_{2,0} = \frac{n(n+1)}{2}$ . The usual substance is represented

by the photons having different frequencies (energy)  $E = h\nu$ , each of them according to the foundational principle of Zeilinger quantum mechanics contains one bit of information.

**Assertion 6.** *During the merger of  $k$  black holes having the same masses  $M_1 = nm_0$  and  $M_2 = nm_0$  and containing the same volumes of information*

$I_1 = \frac{n(n+1)}{2}$  and  $I_2 = \frac{n(n+1)}{2}$ , the absorbing black hole must absorb by  $n^2$  bit information more than contained in the absorbed black hole  $I_2 = \frac{n(n+1)}{2}$  — the absorbing black hole must absorb additionally  $n^2$  particles of usual substance, each of them containing one bit of information.

**Assertion 7.** *The merger of the two black holes having the masses of  $M_1 = n_1m_0$  and  $M_2 = n_2m_0$  and containing the volumes of information  $I_1 = \frac{n_1(n_1+1)}{2}$  and*

$I_2 = \frac{n_2(n_2+1)}{2}$  resulting in one black hole formation, requires the usage of extra  $n_f = n_1n_2$  radiation quanta -  $n_1n_2$  particles of usual substance each of them containing one bit of information.

### 7. Optimal Black Holes

By using informatics approach one can theoretically demonstrate the existence of black holes that minimize information content of arbitrary region of the Universe and place lower bound limitations on information content of the Universe. The origin and cause of optimal black holes existence is the occurrence of substance of two different types: with square-law and linear-law dependence of information content on mass. In the presence of substance of only one type, the optimal black holes do not exist. Following tasks are solved. The direct task: to discover an information minimum in system “usual substance—black a hole” at the given mass of usual substance and a black hole. The dual task: to discover a mass maximum in system “usual substance—black a hole” at the given information in usual substance and a black hole. We examine optimal black hole characteristics in the systems “radiation (photons)—black holes”, “hydrogen (protons)—black holes” and in the system “several types

of usual substance—black holes” [16-24].

#### 7.1. Definition of Optimal Black Holes

Let us estimate the information content of the Universe region of mass  $M_{Un\ rgn}$  under the arbitrary square-law relation between information and energy (mass) of the black hole  $I_{bh} = \alpha \cdot M_{bh}^2$  and arbitrary linear-law relation between information and energy (mass) of usual substance  $I_{us} = \beta \cdot M_{us}$  (under arbitrary non-negative coefficients  $\alpha, \beta$ ). Aggregated information content of the Universe region of mass  $M_{Un\ rgn}$ , consisting of usual substance and one black hole is equal to

$$I_{Un\ rgn} = I_{bh} + I_{us} = \alpha \cdot M_{bh}^2 + \beta \cdot M_{us} \\ = \alpha \cdot M_{bh}^2 + \beta \cdot (M_{Un\ rgn} - M_{bh})$$

Let us find a condition for the minimum:

$$\frac{\partial I_{Un\ rgn}}{\partial M_{bh}} = \frac{\partial (I_{bh} + I_{us})}{\partial M_{bh}} = \frac{\partial (\alpha \cdot M_{bh}^2 + \beta \cdot (M_{Un\ rgn} - M_{bh}))}{\partial M_{bh}} \\ = 2\alpha \cdot M_{bh} - \beta = 0.$$

**Assertion 8.**  $M_{Opt\ bh} = \frac{\beta}{2\alpha}$  is black hole mass, under

which information content of the Universe region of mass  $M_{Un\ rgn}$  consisting of usual substance and one black hole is minimal.

Let’s call the black hole *optimal* under which information content is minimal at the University region of mass  $M_{Un\ rgn}$ , consisting of usual substance and one black hole. Black hole mass does not depend on the mass of the Universe region. Optimal black hole mass is proportional to coefficient correlating information content with usual substance mass and in inverse proportion to coefficient correlating information content with black hole mass.

**Note 5.** Optimal black holes can exist when at least the two types of substance are available in the Universe: with non-linear (for instance,  $I = \gamma \cdot M^\delta$  under  $\gamma > 0, \delta > 1$ ) and linear correspondence between information content and mass.

**Assertion 9.** *Information content of optimal black hole is proportional to squared coefficient correlating information content with mass in usual substance and in inverse proportion to coefficient correlating information*

*content with black hole mass:  $I_{Opt\ bh} = \frac{\beta^2}{4\alpha}$  bits.*

**Note 6.** We will observe a dual task of definition of the maximum mass  $M_{Un\ rgn}$  of system “usual substance—a black hole” at the given information content  $I_{Un\ rgn}$  of the Universe region. Let’s size up mass  $M_{Un\ rgn}$  in the Universe region containing the given information content  $M_{Un\ rgn}$  at the arbitrary square link between the information and energy (mass) of black hole  $I_{bh} = \alpha \cdot M_{bh}^2$  or

$M_{bh}^2 = \frac{1}{\alpha} I_{bh} \left( M_{bh} = \frac{1}{\sqrt{\alpha}} \sqrt{I_{bh}} \right)$ , and the arbitrary linear link between the information and energy (mass) of usual substance  $I_{us} = \beta \cdot M_{us}$  or  $M_{us} = \frac{1}{\beta} I_{us}$  (at the arbitrary nonnegative coefficients  $\alpha, \beta$ ). The information of the Universe region consisting of usual substance and one black hole is equal to  $I_{Un\ rgn} = I_{bh} + I_{us}$ . The mass  $M_{Un\ rgn}$  of the Universe region consisting of usual substance and one black hole, is equal to

$$\begin{aligned} M_{Un\ rgn} &= M_{bh} + M_{us} = \frac{1}{\sqrt{\alpha}} \sqrt{I_{bh}} + \frac{1}{\beta} I_{us} \\ &= \frac{1}{\sqrt{\alpha}} \sqrt{I_{bh}} + \frac{1}{\beta} (I_{Un\ rgn} - I_{bh}) \end{aligned}$$

We will discover an optimality requirement:

$$\begin{aligned} \frac{\partial M_{Un\ rgn}}{\partial I_{bh}} &= \frac{\partial (M_{bh} + M_{us})}{\partial I_{bh}} \\ &= \frac{\partial \left( \frac{1}{\sqrt{\alpha}} \sqrt{I_{bh}} + \frac{1}{\beta} \cdot (I_{Un\ rgn} - I_{bh}) \right)}{\partial I_{bh}} \\ &= \frac{1}{\sqrt{\alpha}} \cdot \frac{1}{2\sqrt{I_{bh}}} - \frac{1}{\beta} = 0. \end{aligned}$$

As  $\frac{\partial^2 M_{Un\ rgn}}{\partial I_{bh}^2} = -\frac{1}{\sqrt{\alpha}} \cdot \frac{1}{4I_{bh}^{3/2}} < 0$  the given requirement is a maximum requirement.

Further we have:  $\frac{1}{\sqrt{\alpha}} \cdot \frac{1}{2\sqrt{I_{bh}}} = \frac{1}{\beta}$ ,  $\frac{\beta}{2\sqrt{\alpha}} = \sqrt{I_{bh}}$

and the information content in a black hole of optimum mass is equal  $I_{bh} = \frac{\beta^2}{4\alpha}$ . The mass of a black hole at

which mass  $M_{Un\ rgn}$  of region the Universe is maximum at the given information content of the Universe region

$I_{Un\ rgn}$ , is equal to  $M_{Opt\ bh} = \frac{1}{\sqrt{\alpha}} \sqrt{I_{bh}} = \frac{1}{\sqrt{\alpha}} \sqrt{\frac{\beta^2}{4\alpha}} = \frac{\beta}{2\alpha}$ .

**Assertion 8.a.** *The Information content in a black hole at which mass of the Universe region  $M_{Un\ rgn}$  consisting of usual substance and one black hole and containing the given information content  $I_{Un\ rgn}$ , it is proportional to a square of coefficient linking an information content with mass in usual substance and inversely proportional to coefficient linking an information content with mass in a black hole:*

$$I_{Opt\ bh} = \frac{\beta^2}{4\alpha} \text{ bits.}$$

**Assertion 9.a.** *The mass of a black hole at which the*

*mass of field of Universe  $M_{Un\ rgn}$  containing the given information content  $I_{Un\ rgn}$  is maximum, consisting of usual substance and one black hole, is equal to*

$$M_{Opt\ bh} = \frac{\beta}{2\alpha}.$$

Information contents and the masses gained at the solution of a direct task (a minimisation of information content in system “usual substance—a black hole” at the given mass of system—assertions 8, 9) and a dual task (a maximisation of mass of system “usual substance—a black hole” at the given information content) assertions 8.a, 9.a), coincide. Thereby concept of an optimum black hole is identical and all subsequent assertions and relationships also are identical.

As far as the black hole mass under which information content is minimal at the Universe region consisting of black hole and common substance does not depend neither on aggregated mass of the Universe (the Universe), nor on usual substance mass in the region under study, then the minimal information content of the Universe region (the Universe) can be reached if the Universe region (the Universe) consists of optimal black holes only. The maximum number of optimal black holes of the Universe region (the Universe) is equal to

$$\begin{aligned} N_{Opt\ Un\ rgn} &= \frac{M_{Un\ rgn}}{M_{Opt\ bh}} = M_{Un\ rgn} \frac{2\alpha}{\beta}, \\ N_{Opt\ bh\ Un} &= \frac{M_{Un}}{M_{Opt\ bh}} = M_{Un} \frac{2\alpha}{\beta}. \end{aligned}$$

The minimal information level of the Universe region (the Universe) consisting of black holes only is equal to

$$I_{Un\ bh} = N_{Opt\ bh} \cdot I_{Opt\ bh} = M_{Un} \cdot \frac{2\alpha \beta^2}{\beta 4\alpha} = \frac{M_{Un} \cdot \beta}{2}.$$

**Note 7.** Hereafter for brevity sake we’ll speak about the Universe, though the assertions and expressions are also true for arbitrary regions of the Universe.

**Assertion 10.** *Minimal information content of the Universe consisting of optimal black holes only is twice as less as information content available of the Universe of the same mass filled with usual substance only:*

$$I_{Un\ bh} = \frac{M_{Un} \cdot \beta}{2} \text{ bits.}$$

Assertions 8 - 10 are true for any kind of linear dependence of information volume on usual substance mass. The important agents of usual substance are radiation and hydrogen. Let’s consider next the optimal black holes characteristics in the systems “radiation (photons)—black holes”, “hydrogen (protons)—black holes”, “several types of usual substance—black holes”.

### 7.2. Universe Filled with Radiation

Let's consider the Universe filled with usual substance (radiation). The energy required for transfer, retrieval, record of one bit under the temperature  $T$  can not be less than the value  $E_{\min} = kT \ln 2$ . In accordance with the Einstein equation, the mass required for transfer, retrieval, record of one bit under the temperature  $T$  can not be less than the value  $M_{\min} = (kT \ln 2)/c^2$ . It is easily seen that for record of 1 bit under  $T = 1$  K the mass no less than  $M_{bit} = E_{bit}/c^2 \approx 10^{-23}$  joule /  $(9 \times 10^{16} \text{ m}^2/\text{s}^2) = 10^{-40}$  kg is needed.

As far as  $\alpha = \frac{2\pi \cdot G}{\hbar \cdot c \cdot \ln 2}$ , and for radiation

$$\beta = \frac{c^2}{k \cdot T \cdot \ln 2}, \text{ then } M_{Opt\ bh} = \frac{\beta}{2\alpha} = \frac{\hbar \cdot c^3}{4\pi \cdot G \cdot k \cdot T} \text{ and}$$

information content of optimal black hole formed in the system "black hole + radiation" is equal to

$$I_{Opt\ bh} = \frac{\beta^2}{4\alpha} = \frac{\hbar \cdot c^5}{8\pi \cdot G \cdot k^2 \cdot T^2 \cdot \ln 2} \text{ bit. Let's express the}$$

obtained result as the following assertion.

**Assertion 11.** Concentration of mass  $M = \frac{\hbar \cdot c^3}{4\pi \cdot G \cdot k \cdot T}$

of optimal black hole minimizes information content in the system "photons—black holes".

We note that the mass of optimal black hole that emerged in the system "radiation—black hole" is in inverse proportion to radiation temperature.

The total number of optimal black holes  $N_{Opt\ bh}$ , in the Universe of mass  $M_{Un}$  consisting of radiation and black holes is equal to

$$N_{Opt\ bh} = M_{Un} \frac{2\alpha}{\beta} = M_{Un} \frac{4\pi \cdot G \cdot k \cdot T}{\hbar \cdot c^3}.$$

**Assertion 12.** The minimal possible information content of the Universe of mass  $M_{Un}$  of the Universe of mass  $M_{Un}$  consisting of radiation and black holes is

$$\text{equal } M_{Un} \frac{c^2}{2 \cdot k \cdot T \cdot \ln 2} \text{ to}$$

$$I_{Un\ min} = I_{Opt\ bh} \cdot N_{Opt\ bh} = \frac{M_{Un} \cdot \beta}{2} \text{ bits.}$$

Thus, the minimal possible information content of the Universe of the Universe of mass  $M_{Un}$  consisting of radiation and black holes is proportional to the mass of the Universe, the speed of light squared, inversely proportional to Boltzman constant and the temperature of the Universe.

**Assertion 13.** The Universe of mass  $M_{Un}$ , consisting of radiation and black holes, containing

$$N_{Opt\ bh} = M_{Un} \frac{4\pi \cdot G \cdot k \cdot T}{\hbar \cdot c^3} \text{ black holes of mass}$$

$M_{Opt\ bh} = \frac{\hbar \cdot c^3}{4\pi \cdot G \cdot k \cdot T}$ , while only each of the black holes of the given mass contains the minimal possible information content equal to

$$I_{Un\ min} = M_{Un} \frac{c^2}{2 \cdot k \cdot T \cdot \ln 2} \text{ bits.}$$

The minimal possible information content of the Universe of mass  $M_{Un}$ , consisting of radiation and black holes is proportional to the energy of the Universe, inversely proportional to Boltzman constant and the temperature of the Universe. It is notable that the minimal information content in the Universe does not depend neither on gravitation constant nor Plank constant

$$M_{Opt\ bh} = \frac{\hbar \cdot c^3}{4\pi \cdot G \cdot k \cdot T} = 9.09 \times 10^{25} \text{ g} = 9.09 \times 10^{22} \text{ kg.}$$

The mass of black hole under which the information minimum is gained in the Universe of mass  $M_{Un}$  consisting of radiation and black holes does not depend on the gross mass of the Universe and is equal to  $9.09 \times 10^{22}$  kg. It is approximately one seventieth of the Earth mass which is equal to  $6 \times 10^{24}$  kg. Information content of optimal black hole is equal to  $I_{Opt\ bh} \approx 1.26 \times 10^{62}$  bits. Our Universe can contain about  $10^{29}$  black holes. The minimal information content in the Universe of the mass equal to the mass  $\approx 10^{52}$  kg of our Universe, consisting of  $10^{29}$  optimal black holes, and only of these, s equal to

$$I_{Un\ min} = N_{Opt\ bh} \cdot I_{Opt\ bh} = \frac{c^2}{2 \cdot k \cdot T \cdot \ln 2} \approx 1.56 \times 10^{91} \text{ bits.}$$

At  $T \approx 2.7 \cdot 10^n$  K the mass of an optimum black hole is approximately equal  $9.09 \times 10^{22-n}$  kg, the information volume in an optimum black hole is approximately equal to  $10^{62-n}$  bits. So at  $T \approx 2.7 \cdot 10^{10}$  K (the nucleosynthesis beginning) mass of an optimum black hole is approximately equal  $10^{13}$  kg, the information volume in an optimum black hole is approximately equal to  $10^{52}$  bits.

**Assertion 14.** Information content of the Universe of mass  $M_{Un} = 10^{52}$  kg consisting of radiation and black holes ranges within  $10^{91} \leq I_{Un\ M} \leq 10^{120}$  bits.

**Assertion 15.** Information content available in the Universe of mass  $M_{Un}$ , consisting of radiation and black holes ranges within

$$M_{Un} \frac{c^2}{2 \cdot k \cdot T \cdot \ln 2} \leq I_{Un} \leq M_{Un}^2 \frac{2\pi \cdot G}{\hbar \cdot c \cdot \ln 2}.$$

### 7.3. The Universe Filled with Hydrogen (Protons)

Let us consider the Universe filled with usual substance (hydrogen). Wave function of proton with upward-di-

rected spin

$$\begin{aligned} \varphi\left(P, s_z = \frac{1}{2}\right) = & \frac{1}{\sqrt{18}}\left(2|p \uparrow\rangle|n \downarrow\rangle|p \uparrow\rangle\right. \\ & + 2|p \uparrow\rangle|p \uparrow\rangle|n \downarrow\rangle + 2|n \downarrow\rangle|p \uparrow\rangle|p \uparrow\rangle \\ & - |p \uparrow\rangle|p \downarrow\rangle|n \uparrow\rangle - |p \uparrow\rangle|n \uparrow\rangle|p \downarrow\rangle \\ & - |p \downarrow\rangle|n \uparrow\rangle|p \uparrow\rangle - |n \uparrow\rangle|p \downarrow\rangle|p \uparrow\rangle \\ & \left. - |n \uparrow\rangle|p \uparrow\rangle|p \downarrow\rangle - |p \downarrow\rangle|p \uparrow\rangle|n \uparrow\rangle\right). \end{aligned}$$

Uncertainty (information content) of proton structure is equal to 2837 bit. Having in mind the uncertainty of spin orientation it is necessary to add 1 bit - 3837 bit. Information content in quarks (1 bit in each) - 3 bit. Colour information content—2585 bit. The total uncertainty (information content) of proton is contained in the proton structure, quarks and colour and equal to 9422 bit.

Hydrogen atom in the ground state  $\left(|IV\rangle = \frac{|+-\rangle + |-+\rangle}{2}\right)$  contains 11.422 bit (1 bit in atomic structure, 9422 bit in proton and 1 bit in electron). As far as  $\alpha = \frac{2\pi \cdot G}{\hbar \cdot c \cdot \ln 2}$ ,

and for hydrogen atoms  $\beta = \frac{11.422}{m_e} \approx \frac{11.422}{m_p}$ , then

$$M_{Opt\ bh} = \frac{\beta}{2\alpha} = \frac{11.422 \cdot \ln 2 \cdot \hbar \cdot c}{4\pi \cdot m_p \cdot G} \text{ and information}$$

content of optimal black hole formed in the system “black hole + hydrogen” is equal to

$$I_{Opt\ bh} = \frac{\beta^2}{4\alpha} = \frac{(11.422)^2 \cdot \hbar \cdot c \cdot \ln 2}{8\pi \cdot m_p^2 \cdot G} \text{ bits.}$$

Let us define the obtained result as the following assertion.

**Assertion 16.** Concentration of mass

$$M_{Opt\ bh} = \frac{11.422 \cdot \ln 2 \cdot \hbar \cdot c}{4\pi \cdot m_p \cdot G} \text{ in the optimal black hole}$$

minimizes information content in the system “hydrogen—black holes”.

The total number of optimal black holes  $N_{Opt\ bh}$ , in the Universe of mass  $M_{Un}$  consisting of hydrogen atoms and black holes is equal to

$$N_{Opt\ bh} = M_{Un} \frac{2\alpha}{\beta} = \frac{4\pi \cdot M_{Un} \cdot m_p \cdot G}{11.422 \cdot \ln 2 \cdot \hbar \cdot c}.$$

**Assertion 17.** The minimal possible information content of the Universe of mass  $M_{Un}$ , consisting of hydrogen atoms and black holes is equal to

$$I_{Un\ min} = I_{Opt\ bh} \cdot N_{Opt\ bh} = \frac{M_{Un} \cdot \beta}{2}$$

$$M_{Un} \frac{11.422}{2 \cdot m_p} = 5.7 \frac{M_{Un}}{m_p} \text{ bits.}$$

Thus, the minimal possible information content of the Universe, of the Universe of mass  $M_{Un}$  consisting of hydrogen atoms and black holes is proportional to the Universe mass and inversely proportional to two masses of hydrogen atom (proton).

**Assertion 18.** The Universe of mass  $M_{Un}$ , consisting of hydrogen atoms and black holes, containing

$$N_{Opt\ bh} = M_{Un} \frac{4\pi \cdot M_{Un} \cdot m_p \cdot G}{11.422 \cdot \ln 2 \cdot \hbar \cdot c} \text{ black holes of mass}$$

$$M_{Opt\ bh} = \frac{11.422 \cdot \ln 2 \cdot \hbar \cdot c}{4\pi \cdot m_p \cdot G} \text{ and only each of the black}$$

holes of the given mass contains the minimal possible information content equal to

$$I_{Un\ min} = 5.7 \frac{M_{Un}}{m_p} \text{ bits.}$$

The minimal possible information content of the Universe, of the Universe of mass  $M_{Un}$ , consisting of hydrogen atoms and black holes is proportional to the mass of the Universe, inversely proportional to hydrogen mass (proton). It is important to note that the minimal information content of the Universe consisting of hydrogen atoms and black holes does not depend on gravity constant, the speed of light and Plank constant.

Let us evaluate the mass of optimal black hole

$$M_{Opt\ bh} = \frac{11.422 \cdot \ln 2 \cdot \hbar \cdot c}{4\pi \cdot m_p \cdot G} = 1.78 \times 10^{14} \text{ g} = 1.78 \times 10^{11} \text{ kg.}$$

Black hole mass, under which the minimum information is gained at the Universe, the Universe of mass  $M_{Un}$  consisting of hydrogen atoms and black holes, does not depend on the gross mass of the Universe and is equal to  $1.776 \times 10^{11}$  kg. This is about the boundary mass of primary black hole equal to  $\approx 10^{12}$  kg. Information content of optimal black hole is equal to

$$I_{Opt\ bh} = \frac{\beta^2}{4\alpha} = \frac{(11.422)^2 \cdot \hbar \cdot c \cdot \ln 2}{8\pi \cdot m_p^2 \cdot G} = 3.76 \times 10^{38} \text{ bits.}$$

There can be about  $10^{41}$  optimal black holes in our Universe. The minimal information content of the Universe whose mass is equal to mass of our Universe of  $\approx 10^{52}$  kg, consisting of  $10^{41}$  optimal black holes and only of these, is equal to

$$I_{Un\ min} = 5.7 \frac{M_{Un}}{m_p} \approx 3.31 \times 10^{79} \text{ bits.}$$

**Assertion 19.** Information content of the Universe of mass  $M_{Un} = 10^{52}$  kg, consisting of hydrogen atoms and black holes lies in the range  $10^{79} \leq I_{Un\ M} \leq 10^{120}$  bits.

**Assertion 20.** Information content of the Universe of

mass  $M_{Un}$ , consisting of hydrogen atoms and black holes lies in the range

$$5.7 \frac{M_{Un}}{m_p} \leq I_{Un} \leq M_{Un}^2 \cdot \frac{2\pi \cdot G}{\hbar \cdot c \cdot \ln 2} \text{ bits.}$$

### 7.4. Maximum Information Content of the Universe

The maximum possible information content is available at the Universe if the latter looks like one black hole of mass  $M_{Un}$ :  $I_{Un \max} = \beta \cdot M_{Un} = \frac{2\pi \cdot G}{\hbar \cdot c \cdot \ln 2} M_{Un}^2$  bits. The maximum information content of the Universe is proportional to squared mass of the Universe, gravity constant, inversely proportional to Plank constant, the speed of light and does not depend on Boltzman constant and the temperature of the Universe. The maximum information content of the Universe represented by one black hole whose mass is equal to mass of our Universe ( $\approx 10^{52}$  kg), is equal to  $I_{Un \max} \approx 10^{120}$  bits.

**Note 8.** Under the radiation temperature

$$T = m_p \frac{c^2}{k \cdot \ln 2 \cdot 9.422} = 1.555 \cdot E + 12 \text{ K}$$

the mass of optimal black holes that emerged in the systems “radiation—black hole” is equal to the mass of optimal black holes that emerged in the systems “hydrogen (protons)—black hole”. By virtue of the fact that stable hydrogen atoms do not exist under high temperatures, then in such case the calculations have been done with respect to protons.

**Note 9.** In the period of transition from the Universe with predominant radiation to the Universe with predominant substance ( $10^4 > T > 10^3$ ), the mass of optimal black hole in the system “radiation—black hole” changes from  $2.45E + 19$  kg to  $2.45E + 20$  kg.

### 7.5. The Systems Consisting of Black Holes and Several Types of Usual Substance

Let us consider the systems consisting of black holes and several types of usual substance, for instance, of various kinds of particles.

From informatics point of view, various types of usual substance differ in coefficient  $\beta_i$  standing for the use of mass per 1 bit of information  $I_i = \beta_i M$ .  $\beta_i$ —denotes information content of the given type of usual substance.

**Assertion 21.** The mass of optimal black hole in the system “several type of usual substance—black holes” under which information content of the system under consideration is getting minimized, is defined by the minimal factor of proportionality  $\beta_{i0} = \min \beta_i$ . The optimal black hole corresponds to the system “usual substance of type  $i_0$ —black holes”.

**Assertion 22.** The mass of black hole under which information content is minimal, meaning information

under which information content is minimal in the system “several type of usual substance—black holes”, is equal to

$$M_{Opt \text{ bh}} = \frac{\beta_{i0}}{2\alpha}.$$

**Assertion 23.** Information content of optimal black hole in the system “several types of usual substance—black holes” is proportional to squared minimal coefficient correlating information content with mass in different types of usual substance and inversely proportional to coefficient correlating information content with mass in black hole:  $I_{Opt \text{ bh}} = \frac{\beta_{i0}^2}{4\alpha}$  bits.

As the black hole mass under which information content is minimal in the system “several types of usual substance—black holes”, does not depend on neither on the total mass of the system  $M$ ,  $M$ , nor on the mass of usual substance, then the minimum information content of the Universe is gained if the system consists of optimal black holes only. The maximum number of optimal black holes in the system “several types of usual substance—

$$\text{black holes}” N_{Opt \text{ bh}} = \frac{M}{M_{Opt \text{ bh}}} = M \frac{2\alpha}{\beta_{i0}}.$$

The minimum information content in the system “several types of usual substance—black holes”, consisting of black holes only is equal to

$$I_M = N_{Opt \text{ bh}} \cdot I_{Opt \text{ bh}} = M \cdot \frac{2\alpha}{\beta} \frac{\beta^2}{4\alpha} = \frac{M \cdot \beta_{i0}}{2}.$$

**Assertion 24.** If optimum black holes are formed of various types of atoms of usual substance or a mix of various types of atoms of usual substance masses of optimum black holes and volumes of the information in them are approximately identical.

## 8. Conclusions

1) A black hole is the aggregate of particles (black particles) each having a mass equal to 0.23th of Planck mass) and interacting with all other black particles that form a black hole.

2) The volume of information in the black hole is proportional to the square of the mass black hole, and presents information characteristics of black holes of different masses.

3) The temperature of the radiation of a black hole coincides up to a factor  $\frac{2 \ln 2}{2.7} \approx 0.51$  with an estimate of

$$\text{Hawking } T_H = \frac{\hbar \cdot c^3}{8\pi \cdot k \cdot G \cdot M}.$$

4) Black hole cannot be created by means of merging the two black holes and only two black holes. Merging of

black holes can occur only with the absorption and emission of usual substance.

5) During the merger of two black holes having the masses  $M_1 = n_1 m_0$ ,  $M_2 = n_2 m_0$ , without using any additional usual substance, the mass of a newly formed black hole is less than

$$M_{1+2} = \sqrt{n_1(n_1+1) + n_2(n_2+1)} m_0 \\ \approx \sqrt{n_1^2 + n_2^2} m_0 = \sqrt{M_1^2 + M_2^2}.$$

6) The occurrence of substance of two types: with square-law and linear-law dependence of information content on mass—is the origin and cause of optimal black holes existence that minimize information content in the arbitrary region of the Universe as well as of the Universe as a whole.

7) Considers the characteristics of optimal black holes in the systems “radiation (photons)—black holes”, “hydrogen (protons)—black holes” and in the systems “several types of usual substance—black holes”.

8) Black hole mass under which the minimum information content is gained at the Universe of mass  $M_{Un}$  consisting of radiation and black holes, does not depend on the gross mass of the Universe and is equal to  $9.09 \times 10^{22}$  kg. It is approximately one seventieth of the Earth mass. Information content of optimal black hole is equal to  $\approx 1.26 \times 10^{92}$  bits. Our Universe can contain about  $10^{29}$  such optimal black holes. The minimum information content of the Universe is equal to  $\approx 10^{91}$  bits.

9) Black hole mass under which the minimum of information content is gained at the Universe consisting of hydrogen atoms and black holes, does not depend on the gross mass of the Universe and is equal to  $1.78 \times 10^{11}$  kg. Information content of optimal black hole is equal to  $3.76 \times 10^{38}$  bits. The minimum information content of the Universe whose mass is equal to the mass of our Universe that is  $\approx 10^{52}$  kg, consisting of approximately  $10^{41}$  optimal black holes and only of these, is equal to  $\approx 10^{79}$  bits.

10) The maximum possible information content is available at the Universe if the latter appears to be one black hole. In this case it is equal to  $\approx 10^{120}$  bits.
