Abstract
In this paper, the artificial generation of elementary catastrophe optics having odd codimensions \( K = 1, 3 \) and \( 5 \) such as the Fold, the Swallowtail and the Wigwam diffraction caustics is investigated theoretically. It is shown that the integral catastrophes with odd polynomials phase functions can be reduced to the well-known Airy-Hardy cosine integrals. In this connection, the caustic functions of the Fold, Swallowtail and Wigwam caustic beams are expressed in closed-form in terms of Airy-Hardy cosine functions. An optical method based on the Fourier transform similar to that described by Lohmann et al. [Optics Comm. 109 (1994) 361-367] is proposed for the generation of the Fold, Swallowtail and Wigwam caustic beams. The displaying of the catastrophe patterns with \( K = 1, 3 \) and \( 5 \) is optically implemented in the Fourier transform device by using simple binary screens with tailored polynomials transmission.

Subject Areas
Photochemistry

Keywords
Fold Caustic, Swallowtail Caustic, Wigwam Caustic, Airy-Hardy Integrals, Fraunhofer Diffraction Pattern, Catastrophes Optics

1. Introduction
In recent years, a lot of researches have been devoted to the nonconventional applications of optical computing [1]-[17]. In fact, different binary patterns have been used in many optical devices to implement intriguing phase profiles and for generating the complex amplitudes of the well-known catastrophe functions.
The application of spatial light modulators has permitted the experimental realization of some artificial catastrophes in optics, e.g., the fundamental catastrophe beams such as the Airy (Fold) and Pearcey caustic modes [5] [16] [17]. It is well established in the catastrophe theory [18] [19] [20] [21] [22] that the catastrophe functions can be described by seven elementary structures which are classified according to their codimensions $K$. The caustic beams emerging as diffraction catastrophes are particular solutions of the paraxial Helmholtz equation, and they can be expressed in the typical integral representation [18] [19] [20] [21] [22].

$$\Psi_n(C) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} e^{i\phi_n(x;C)} ds,$$

(1a)

where

$$\phi_n(x;C) = s^n + \sum_{j=1}^{n-2} C_j s^j,$$

(1b)

where $s$ represents the state variable, $C_j$ are the $n-2$ control parameters and $\phi_n$ is the catastrophe phase polynomial of n-th order that depends on the state variable $s$ and the control parameters $C_j$ with the codimension $K = n-2$.

The three members of the hierarchy catastrophe structures that we will examine in this paper are given in Table 1, where we have listed the considered diffraction catastrophes with the corresponding phase polynomials $\phi$ and codimensions $K$. For the sake of comparison we have reported, the Berry’s [18] and Stewart’s [19] unfolding phase polynomials.

By using the change of the variable $x = \frac{s}{N^{1/5}}$, one obtains the relationship between the control parameters $C$ and $\Delta$ in the Refs. [18] and [19]. For $K = 1$, the phenomenon is called Fold diffraction caustic, we have

$$C = \frac{a}{3^{1/5}},$$

and the structure function $\psi_1(C)$ is proportional to the well-known Airy function.

where the Airy function is defined as [23],

\[
Ai(x) = \frac{1}{\pi} \int_{0}^{\infty} dt \cdot \cos \left( \frac{t^3}{3} + xt \right).
\]

For \( K = 3 \), the phenomenon is called Swallowtail diffraction catastrophe [24] [25] [26] [27] [28], so we have

\[
C_1 = \frac{1}{5\pi} c, \quad C_2 = \frac{2}{5\pi} b, \quad C_3 = \frac{3}{5\pi} a,
\]

and the caustic function reads

\[
\psi_3(C_1, C_2, C_3) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{+\infty} ds \cdot e^{\left( \frac{s^3}{3} + C_1s^3 + C_2s^3 + C_3s^3 \right)}.
\]

The case \( K = 5 \) corresponds to the so-called Wigwam diffraction catastrophe [24] and we obtain the following identities

\[
C_1 = \frac{1}{7\pi} e, \quad C_2 = \frac{1}{7\pi} d, \quad C_3 = \frac{3}{7\pi} c, \quad C_4 = \frac{4}{7\pi} b \text{ and } C_5 = \frac{5}{7\pi} a.
\]

and

\[
\psi_5(C_1, C_2, C_3, C_4, C_5) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{+\infty} ds \cdot e^{\left( \frac{s^5}{5} + C_1s^5 + C_2s^5 + C_3s^5 + C_4s^5 + C_5s^5 \right)}.
\]

It is worth noting that, apart from the case \( K = 1 \), the caustic functions \( \psi_a \) above haven’t been expressed, to the best of our knowledge, in terms of well-known mathematical functions. In the remainder of the paper, we will show the relationship between these catastrophe functions and the Airy-Hardy integrals, and propose an optical method by using tailored binary screens, for the creation of the elementary optical catastrophes of odd codimensions (\( K = 1, 3 \) and 5).

2. Caustic Functions and Their Connection with the Airy-Hardy Integrals

One can note that for particular values of the control parameters, the phase functions in Equations (6) and (7) are reduced to odd polynomials, and thus the associated catastrophe functions are proportional to the Airy-Hardy cosine integrals [23]. In fact, if one takes \( C_2 = 0 \) in the case \( K = 3 \), or \( C_2 = C_4 = 0 \) for \( K = 5 \), the associated phase polynomials \( \phi_3 \) and \( \phi_5 \) will be odd functions, then it will be simpler to express the caustic functions (\( K = 1, 3 \) or 5) as

\[
\psi_3(C) = \frac{1}{\sqrt{2\pi}} \int_{0}^{\infty} ds \cdot \cos \left( \frac{s^3}{3} + Cs \right),
\]

\[
\psi_5(C_1, C_3) = \frac{2}{\sqrt{2\pi}} \int_{0}^{\infty} ds \cdot \cos \left( \frac{s^5}{5} + C_1 \frac{s^3}{3} + C_3 s \right).
\]
These last integrals belong to the Airy-Hardy integrals class and then they can be expressed in the canonical form [22] [23]

\[ \psi_{\alpha}(C_1, C_2, C_3) = \frac{\pi^{3/2}}{\sqrt{2\pi}} \prod_{i=0}^{n} \cos \left( \frac{s_i^2}{7} + C_i \frac{s_i^5}{5} + C_i \frac{s_i^3}{3} + C_i s_i \right). \]  

(10)

Hobbs et al. [23] have expressed these solutions in terms of Bessel functions of fractional orders as

\[ Ch_\alpha(n) = \left\{ \begin{array}{ll}
J_{\alpha \pi n} \left( 2\alpha \frac{n^{1/2}}{\pi} \right) - I_{\alpha \pi n} \left( 2\alpha \frac{n^{1/2}}{\pi} \right) & \text{for } \alpha > 0 \\
J_{-\alpha \pi n} \left( 2\alpha \frac{n^{1/2}}{\pi} \right) + I_{-\alpha \pi n} \left( 2\alpha \frac{n^{1/2}}{\pi} \right) & \text{for } \alpha < 0
\end{array} \right. \]  

(14)

where \( J_v \) and \( I_v \) are the \( v \)-th order Bessel and the modified Bessel functions of the first kind, respectively.

For \( \alpha = 0 \), the approximate value of \( Ch_\alpha(\alpha) \) reads

\[ Ch_\alpha(0) \approx \frac{2}{(2n+1) \Gamma \left( \frac{1}{2n+1} \right) \cos \left( \frac{\pi}{2(2n+1)} \right) \prod_{i=0}^{n} \cos \left( \frac{s_i^2}{7} + C_i \frac{s_i^5}{5} + C_i \frac{s_i^3}{3} + C_i s_i \right)}, \text{ for } n = 1, 2 \text{ and } 3 \]  

(15)

By putting \( \alpha = \frac{C}{3^{1/3}} \) and using the similarity between the Equations (11b) and (16a), we obtain

\[ \psi_{\alpha}(\alpha) = \frac{3^{1/3}}{\sqrt{2\pi}} Ch_\alpha(\alpha). \]  

(16)
The integral expression of Equation (9) can be rewritten

\[ \psi_s(C_1, C_3) = 2 \cdot \frac{5^{1/5}}{\sqrt{2\pi}} \int_0^{\infty} dt \cdot \cos \left(t^5 + \frac{C_1}{3} \cdot 5^{1/5} t^3 + C_3 \cdot 5^{1/5} t \right). \]  

(17a)

If we take \( \frac{C_1}{3} \cdot 5^{1/5} = 4\alpha \) and \( C_3 = 5\alpha^2 \), the last diffraction integral reduces to

\[ \psi_s(\alpha) = 2 \cdot \frac{5^{1/5}}{\sqrt{2\pi}} \int_0^{\infty} dt \cdot \cos \left[T_i(t, \alpha) \right], \]  

(17b)

or equivalently

\[ \psi_s(\alpha) = \frac{5^{1/5}}{\sqrt{2\pi}} Ch_b(\alpha). \]  

(17c)

The Wigwam catastrophe integral can also be expressed as

\[ \psi_s(\alpha) = 2 \cdot \frac{7^{1/7}}{\sqrt{2\pi}} \int_0^{\infty} dt \cdot \cos \left(t^7 + \frac{C_3}{5} \cdot 7^{1/7} t^4 + C_3 \cdot 7^{1/7} t \right). \]  

(18a)

By putting \( 7\alpha = \frac{7^{1/7}}{5} C_3, 14\alpha^2 = \frac{7^{1/7}}{3} C_3, 7\alpha^3 = 7^{1/7} C_3 \), this leads to

\[ \psi_s(\alpha) = \frac{7^{1/7}}{\sqrt{2\pi}} Ch_7(\alpha). \]  

(18b)

We inferred from the above procedure that the caustics of odd codimensions \( K = 1, 3 \) and 5 are connected to the Hardy-Airy functions of orders \( n = 3, 5 \) and 7, respectively. In the forthcoming section, we will be interested in displaying in optical way these non-conventional functions.

3. Generation of the Elementary Optical Catastrophes with \( K = 1, 3 \) and 5

Based on the fact that the complex caustic structures are expressed in terms of polynomial phase functions, we adopt an optical technic similar to that employed by Lohmann et al. [2] [3] for implementing Airy, Bessel and Laguerre functions. The proposed setup is a Fourier transformer whose schematic diagram is given in Figure 1: A plane wave front illuminates a binary screen which is transparent only along the curve \( y = F(x) \) on the \( XY \) plane. Thus, the transmittance function \( T(x, y) \) in the binary screen can be expressed as

\[ T(x, y) = \delta(y - F(x)), \]  

(19)

where \( F(x) \) is the curve profile and \( \delta(\cdot) \) is the Dirac function.

The amplitude distribution of the Fraunhofer diffraction pattern in the back focal plane of the lens \( L \) is obtained by taking the Fourier transform of Equation (19). This leads to

\[ \tilde{T}(v, \mu) = \int \int T(x, y) e^{-2\pi i (xv + y\mu)} dx dy. \]  

(20a)
Figure 1. Diagram of the optical setup: at the input plane $XY$ a binary screen with the transmittance $T(x,y) = \delta(y - F(x))$ illuminated by a plane wave. Detector for output pattern at the back focal plane of the lens $L$.

Substituting from Equation (19) into Equation (20a) and using the integral property of the Dirac function yields

$$\hat{T}(v,\mu) = \int_{-\infty}^{\infty} dx e^{-2i\mu y F(x)}.$$ (20b)

It is worth noting that Equation (20b) is a typical integral representation for many special functions employed in lasers physics, e.g., the Airy, Bessel, Laguerre functions [2] [3]. In particular, if $F(x)$ is odd function, the Equation (20b) can be rewritten as

$$\hat{T}(v,\mu) = \int_{-\infty}^{\infty} dx \cos 2\pi(vx + \mu F(x)).$$ (21)

In the following, we propose the transmission profiles that may create oscillating integral patterns encountered in many fields, e.g., in physics, chemistry and biology.

3.1. The Fold Catastrophe Pattern

First, let us consider a mask transmission profile of the form $T(x,y) = \delta(y - \sigma x^3)$, where $\sigma$ is an arbitrary constant (Figure 2(a)).

The Fourier transform of this input amplitude can be written as

$$\hat{T}_f(v,\mu) = 2(\sigma\mu)^{-\frac{1}{3}} Ch_3\left(\frac{\alpha}{3^{\frac{2}{3}}\nu}\right),$$ (22)

with $\alpha = \frac{v}{3}(\sigma\mu)^{-\frac{1}{3}}$. The irradiance distribution of the Fraunhofer pattern in the output plane is depicted in Figure 2(b).

By placing a narrow slit in the output plane along the $\nu$-axis, at $\mu = \eta$ just behind the slit, the output diffracted amplitude reads

$$\hat{T}_f(v,\eta) = \hat{T}_f(v,\mu)\delta(\mu - \eta) = 2(\sigma\eta)^{-\frac{1}{3}} Ch_3\left(\frac{(\sigma\eta)^{-\frac{1}{3}}}{3^{\frac{2}{3}}}\nu\right).$$ (23)

It follows from this last equation that by displacing the slit to arbitrary values...
Figure 2. (a) Input binary pattern with $F(x) = \sigma \cdot x^3$, (b) associated output Fraunhofer pattern, and (c) square modulus of Airy-Hardy $Ch_2(x)$ with $\nu = 2$. 
of $\eta$, one can produce the Hardy-Airy function $Ch_3(\cdot)$ along the $\nu$-axis. Figure 2(c) shows the irradiance of $Ch_3(\cdot)$ which is consistent with the well-known Airy function, with an arbitrary $\eta$.

### 3.2. The Swallowtail Catastrophe Pattern

Now, by considering the curve function $F_s(x)$ of the form (Figure 3(a))

$$F_s(x) = px^3 + qx^5,$$  \hfill (24a)

where $p$ and $q$ are arbitrary constants, the Fourier transform of the associated input amplitude reads

$$\hat{T}_s(\nu, \mu) = 2 \int_0^{+\infty} dx \cos \left(2\pi\nu x + 2\pi\mu px^3 + 2\pi\mu qx^5\right).$$  \hfill (24b)

Making the change of the variable $x = a^{-1/5} t$, with $a = 2\pi\mu q$, this leads to

$$\hat{T}_s(\nu, \mu) = 2a^{-1/5} \int_0^{+\infty} dr \cos \left(t^5 + 2\pi\mu pa^{-1/5} t^3 + 2\pi\mu qa^{-1/5} t\right).$$  \hfill (25)

Putting $4\alpha = 2\pi\mu p \cdot a^{-1/5}$ and $5\alpha^2 = 2\pi\nu d^{-1/5}$, and after some algebraic operations, Equation (25) is reduced to

$$\hat{T}_s(\nu, \mu) = \hat{T}(\alpha) = 2a^{-1/5} Ch_3(\alpha).$$  \hfill (26)

Reciprocally, one can write

$$Ch_3(\alpha) = \frac{1}{2} \left(2\pi\mu q\right)^{1/5} \hat{T}_s(\nu, \mu).$$  \hfill (27)

The irradiance distribution of the Fraunhofer pattern of the input amplitude is shown in Figure 3(b). By placing a narrow slit along the $\nu$-axis at $\mu = \xi$, just behind the slit, the resulted amplitude reads

$$\hat{T}_s(\nu, \xi) = \hat{T}_s(\nu, \xi) \delta(\mu - \xi) = 2 \left(2\pi\xi q\right)^{-1/5} Ch_3\left(\frac{5}{4} \frac{\nu}{\xi} p \left(2\pi\xi q\right)^{3/5}\right).$$  \hfill (28)

Hence, one can visualize the profile of the Hardy-Airy function $Ch_3(\alpha)$ along the $\nu$-axis. Figure 3(c) shows the irradiance profile proportional to $Ch_3(\alpha)$ with $\nu = 2$.

### 3.3. The Wigwam Catastrophe Pattern

By considering the mask transmission function $F_w$

$$F_w(x) = px^7 + qx^5 + rx^3,$$  \hfill (29)

where $p$, $q$ and $r$ are arbitrary constants, its Fourier transform is given by

$$\hat{T}_w(\nu, \mu) = 2 \int_0^{+\infty} dx \cos \left(2\pi\nu rx^7 + 2\pi\mu px^3 + 2\pi\mu qx^5 + 2\pi\nu x\right).$$  \hfill (30)

Now, making the change of variable $x = b^{-3/7} t$, with $b = 2\pi\nu r$, and by taking

$$7\alpha = \frac{C_5}{5} \gamma^{1/7} = 2\pi\mu qb^{-3/7}, \quad 14\alpha^2 = \frac{C_3}{3} \gamma^{5/7} = 2\pi\mu pb^{-3/7},$$

DOI: 10.4236/oalib.1105958 8 Open Access Library Journal
Figure 3. (a) Input pattern with $F(x) = p \cdot x^3 + q \cdot x^4$, (b) associated output Fraunhofer pattern and (c) square modulus of Airy-Hardy $Ch_2(x)$ with $\nu = 2$. 
\[ 7\alpha^3 = C_1 7^{\frac{1}{17}} = 2\pi v b^{\frac{1}{17}}, \] Equation (30) can be expressed as

\[ \hat{T}_\nu(v, \mu) = 2 \cdot b^{\frac{1}{17}} Ch_\nu(\alpha), \] (31)

or equivalently

\[ Ch_\nu(\alpha) = \frac{1}{2} (2\pi \mu q)^{\frac{1}{17}} \hat{T}_\nu(v, \mu). \] (32)

Following the same procedure as described in Sections (3.1) and (3.2) and using the binary mask of Equation (29), we have displayed the irradiance distribution of the Fraunhofer pattern associated with \( Ch_\nu(\cdot) \) in Figure 4(c). It is

**Figure 4.** (a) Input pattern with \( F(x) = p \cdot x^2 + q \cdot x^3 \), (b) associated output Fraunhofer pattern and (c) square modulus of Airy-Hardy \( Ch_\nu(x) \) with \( \nu = 2 \).
worth noting that the patterns of Figure 2(c), Figure 3(c) and Figure 4(c) can be controlled by adjusting the parameters $\sigma, p, q, r$; e.g., a negative value of $\sigma$ will give the symmetrical profile of Figure 2(c).

The parameter $\sigma$ can be regarded as a scaling length for controlling the Fraunhofer pattern structure of Figure 2(b), and in the same way, different mapping caustics for Swallowtail and Wigwam optical catastrophes (Figure 3(c) and Figure 4(c)) can be performed, globally, by varying the scaling parameters $p, q$ and $r$ of the binary amplitude transmittance in the input plane. This procedure may permit application opportunities in micromachining on tailored curves and light guiding paths.

### 4. Conclusion

In summary, based on the fact that the integral diffraction catastrophes can be reduced in the case of odd polynomials phase functions into Airy-Hardy cosine integrals, we obtained the closed-form expressions for the related caustic functions. We showed that by the use of an optical Fourier Transformer device with tailored binary screens one can obtain the displaying of caustic beams such as the Fold, the Swallowtail and the Wigwam catastrophes. Furthermore, it is shown that the mapping caustics for Swallowtail and Wigwam caustics can be controlled by the scaling parameters $p, q$ and $r$ of the binary mask transmittance. The result of this work can be useful in shaping lasers with catastrophe amplitude function and may have application opportunities in micromachining and light guiding paths. This study can be extended to higher oscillatory integral functions.
